Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

Local Anæsthesia in Surgical Practice

CLEFT PALATE AND HARE-LIP.

Typical Cases.

K. E., aged 26 years.
Diagnosis: Cleft palate and hare-lip.
Operation: Plastic repair.
Anæsthesia: 60 c.c. of a 2 per cent. Novocain-Adrenaline solution were used. The anæsthesia was ideal. Healing was perfect throughout the line of suture.

A. M., aged 15 years.
Diagnosis: Cleft palate.
Operation: Plastic repair.
Anæsthesia: Local infiltration, Novocain-Adrenaline 2 per cent. Under ideal anæsthesia this complete cleft was repaired, and the repair was followed by primary healing. The boy had been operated upon twelve years previously, and, notwithstanding the presence of scar tissue, perfect anæsthesia was obtained.

—Extracts from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of these and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

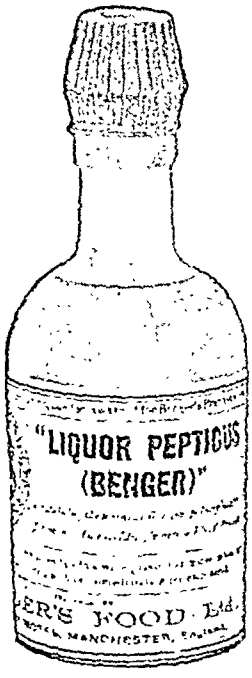
ESSENCE of RENNET

CONCENTRATED (BENGER).

(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.



LIQUOR PEPTICUS

(BENGER).

"A digestive agent of extraordinary power."

Sir William Roberts, M.D., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

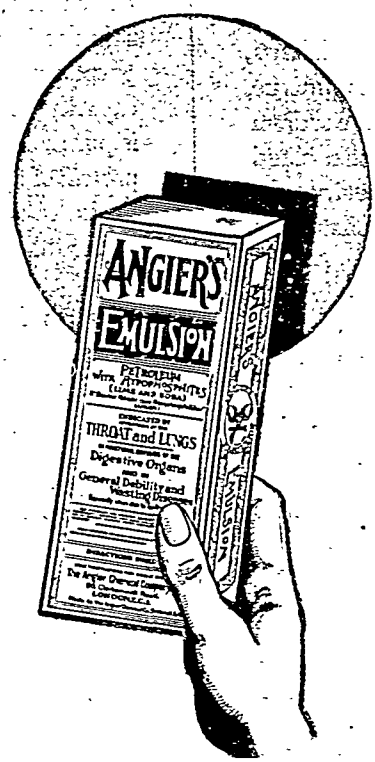
REGD. TRADE MARK.

Bronchitis, Winter Cough,

Influenza and Sequelae.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing, "comforting" effects.



The unique soothing properties of Angier's Emulsion, its favourable influence upon assimilation and nutrition, and its general tonic effects, make it eminently useful both during and after influenza. It has a well-established reputation for efficiency in relieving the troublesome laryngeal or tracheal cough, correcting the gastro-intestinal symptoms and combating the nervous depression and debility.

Disturbances of Menstruation and the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases.

The chemical composition of Kalzana, calcium - sodium - lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is supplied in a convenient tablet form, is free from harmful by-effects and is pleasantly flavoured.

Dispensed by Chemists in air-tight packets containing 50 and 100 Tablets.

Kalzana

Exactitude in preparing Milk Mixtures

very often solves the most difficult problems set by the artificially-fed infant. Careful dilution of cow's milk will give the correct percentage of casein, and the addition of Albulactin provides exactly the proportion needed to meet the digestive capacity of the infant. Albulactin is pure soluble lactalbumin—the vital proteid of milk—upon which depends the formation of a fine, flocculent curd in the infantile stomach. Albulactin simplifies the preparation of milk mixtures for all infants, from the premature weakling to the normal healthy baby.

"The British Medical Journal" says:

"A modified milk, prepared by mixing cow's milk, albulactin, and water in such proportions that the casein and albulactin were in approximately equal amounts, formed much less curd when acidified than diluted cow's milk, containing the same proportion of total protein. There appears to be every reason to expect this preparation to be of great value in the hand feeding of infants."

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

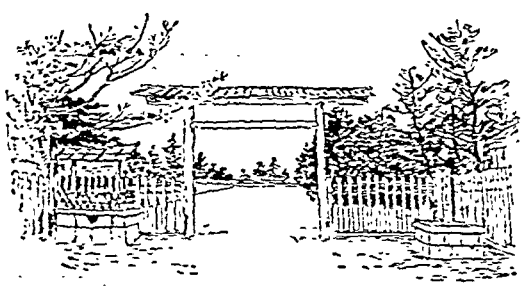
ENTRANCE TO THE TOMB OF JIMMU, THE LEGENDARY FOUNDER OF THE EMPIRE OF JAPAN.—There are no written annals until the early seventh century A.D., but Jimmu's immigration is one of those for which archæologists have fixed c. 1000 to 500 B.C. as a likely era. Jimmu is represented as reminding his kith and kin that 1,792,470 years previously Japan had been given to their Heavenly ancestor. He then adds: "But the remote regions do not yet enjoy the blessings of imperial rule. Every town has always been allowed to have its lord, and every village its chief, who, each one for himself, makes division of territory and practises aggression and conflict. I think that this land will undoubtedly be suitable for the extension of the Heavenly task so that its glory will fill the universe. It is doubtless the centre of the universe. Why should we not proceed thither and make it the capital?" Jimmu became emperor and probably succeeded in some degree in welding the clans together and giving them their earliest idea of unity. The spot approached through the entrance here reproduced, is recognised officially by the Japanese as the tomb of their first Mikado; every year on April 3rd, an imperial envoy visits it and makes offerings of produce from mountain, river and sea.



Date: (Legendary) 660 B.C.

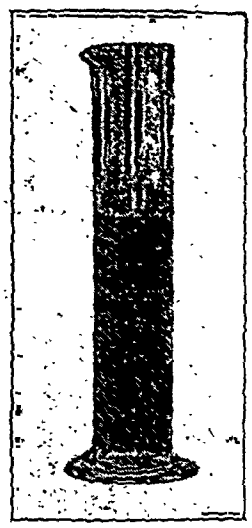
The 'Allenburys' DIET

A Stimulating and Sustaining Food Beverage

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

An Address
ON
UNUSUAL SYMPTOMS DUE TO ENLARGEMENT OF THE PROSTATE.*

BY
G. GREY TURNER, M.S., F.R.C.S.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF DURHAM.

THIS address is not intended for genito-urinary specialists, or even for operating surgeons, but for those among you who are general practitioners, whose duty it is to see patients at the outset of their troubles and assume responsibility for their diagnosis. Further, what I have to say is entirely from the point of view of the general surgeon, for, though I have always been interested in genito-urinary disease, I have not devoted especial attention to this branch of practice.

I have always been alive to the importance of the problems of disease as they are presented by the "patients' complaints," and my responsibility as a teacher of medical students, who are most of them to become the practitioners of the future, has made me pay particular attention to this aspect of our work. Most of us must have recognized the difficulty of getting clinical knowledge from books, for the descriptions of diseases, as we read them, have been pieced together from many cases. Quite a limited experience of practice of any kind soon teaches how much actual "patients" differ from "cases." Similarly, experience has taught me that a whole variety of symptoms not obviously connected with the urinary system may depend on enlargement of the prostate, and it is to this aspect that I particularly wish to refer.

USUAL SYMPTOMS OF ENLARGED PROSTATE.

As I was putting together my notes it seemed to me that perhaps it would avoid misunderstanding if I enumerated quite briefly the "usual" sort of symptoms which bring patients suffering from enlargement of the prostate under the care of the surgeon. Of course, I fully realize how easy it may be for anyone, like myself, working principally in large hospitals to get ideas on disease which are different from those obtained in general practice. At the same time, practically all the cases are sent into hospital by the practitioners of the district in which I live, so that they represent the problems with which they have to deal.

At the outset I would like to emphasize the truth of the dictum laid down by Sir Henry Thompson, to the effect that enlargement of the prostate of such a degree as to give rise to symptoms demanding treatment does not occur before 50 years of age. It has been quite surprising to me, but it is none the less true, that in an experience of over thirty years I have never yet seen a case of ordinary enlargement of the prostate, that is, non-malignant, except in those over this age.

Now the usual prostatic symptoms can be arranged under one or other of the following heads:

Hesitation in starting and finishing the act of micturition.
Irritability and frequency, with dribbling.
Mostly nocturnal frequency.
Attacks of retention.
A culminating attack of complete retention.
Retention with overflow, and any combination of the above.

I do not doubt that there are other symptoms which will at once stamp the patient as suffering from urinary trouble, probably of prostatic origin, and those whose reputation particularly attracts urinary cases will often be consulted by people complaining of very early symptoms associated with prostatic enlargement, but these are less definite and are not always easy to assign to their proper cause.

UNUSUAL SYMPTOMS OF ENLARGED PROSTATE.

And now I want to draw attention to the unusual symptoms which I have promised to discuss.

Early in my career my attention was attracted to this matter by the case of a man whom I saw in consultation with his family doctor, because he was supposed to be suffering from gastric carcinoma.

This patient, a man aged 67, stated that he had usually been healthy, suffering only from occasional bilious attacks in which he would have vomiting perhaps for a day. Eighteen months before I saw him he had his first real stomach illness when he was laid up for several weeks; it was exactly similar to the attack for which I was consulted. At the same time he was found to be suffering from enlargement of the prostate. His doctor taught him to pass a catheter, but he soon gave that up and had to rise twice every night to micturate. Between that illness and the present one he considered himself perfectly well. About five months before the consultation he began to have pain in the stomach about two hours after every meal. The pain would continue until he was due to take the next meal, but more food always relieved the pain. It was situated about the pit of the stomach and extended upwards towards the chest. When the pain was bad he sometimes brought up a mouthful or more of food, but it was usually watery fluid, and he had only once brought up a little blood. These symptoms continued, and he had lost weight and strength. There had never been any difficulty in swallowing.

When seen the patient was found to be of big, strong build, but obviously not in good health and showing evidence of recent loss of flesh. Occasionally a little gurgling could be made out over the stomach area, but no mass was to be felt, and there was no evidence of gross dilatation nor was there any tender area. There was no fluid in the abdomen, and nothing abnormal could be made out per rectum. An œsophageal bougie easily entered the stomach, the contents showed free hydrochloric acid, and an absence of lactic acid. It was before the days when x rays were regularly used in gastric cases. The prostate was found to be definitely enlarged, and later his doctor drew off about 14 oz. of residual urine.

As a method of preliminary treatment the bladder was emptied by catheter night and morning. Subsequently the prostate was removed, and this accomplishment was followed by the complete disappearance of all the stomach symptoms.

For the purpose of operative treatment this man was admitted as a case of enlarged prostate to a general hospital, and it is interesting to read the notes made by the clerk entirely from the genito-urinary standpoint, for there is not one word about the stomach symptoms which first sent the patient to his doctor!

This experience occurred over twenty years ago, and in the intervening period I have frequently seen similar cases. A recent example is quite typical, and will serve as a further illustration.

One day I was making a brief visit to my wards accompanied only by the sister, a most experienced nurse whose diagnosis is rarely at fault. In passing one of the beds she asked me to look at a man, 62 years of age, who had been admitted as a case of malignant stomach, and whom she thought looked like it. He certainly appeared to be older than his years, and was white, haggard, and neglected. All his complaint was of a bad stomach, and he put his hands over the epigastrium as the seat of his trouble. I found that the following notes had been made by the house-surgeon:

"Patient admitted complaining of vomiting after meals for past twelve months; no pain; appetite good; loss of weight; bowels regular; no blood seen. *Examination:* Patient very wasted and looks ill. Abdomen retracted: no definite irregularity. No mass, but tenderness in epigastrium."

As I saw him the man showed signs of recent loss of weight, but I could find nothing on hastily examining the abdomen, and certainly there was no mass in the stomach region. I remarked to the sister that he looked like a prostatic case, and asked her to get the house-surgeon to investigate the patient with that possibility in view. Sure enough he found a very big prostate and residual urine measuring 23 oz. Subsequently the bladder was opened suprapubically and drained. Palpation of the gland suggested that it was probably malignant. This man got great temporary relief, and all his stomach symptoms at once disappeared.

At this stage I would like to draw attention to the value of bimanual examination as a means of detecting the presence of residual urine, when perhaps it is not convenient to test for the latter in the usual way. Of course, the patient must first pass as much urine as possible under the most comfortable circumstances, and I would remind you that few people can do justice to themselves when lying on their backs in bed. When as much urine as possible has been voided the bladder may not be felt distended either from above or from the rectum, but bimanually it may be felt to be as big as a cricket ball, or larger, indicating that it contains from 4 to, say, 10 oz. of residual urine.

Of course, these cases are for the most part sufficiently obvious when the circumstances have been sifted, but difficulties arise, either because patients disguise from themselves sometimes—and certainly from their medical attendant—the fact that there is any urinary abnormality, or because the interpretation which they themselves put upon their symptoms leads them to believe that any urinary

*Given before the Medical Society at Nottingham, December 5th, 1928.

difficulty is a secondary factor and not the real source of their troubles.

I am sure we have all recognized that the art of diagnosis is allied to the craft of the detective, and I hope you will not be surprised when I tell you that I am accustomed to recommend to my class as guides to diagnosis *The Adventures of Sherlock Holmes*, and a little book called *Aids to Scouting* by Baden-Powell.

Now the next case, whose history I obtained from the patient after he had been operated upon, appears consecutive and reasonable enough, but, as a matter of fact, when this patient consulted his medical man, and subsequently a physician, his mind was made up that the cause of his trouble was associated with some bronchial catarrh due to cold, and, on another occasion, to an increasing dyspepsia, and on neither occasion did he volunteer any information about his urinary difficulty. He was just the type of individual who had always been self-reliant and introspective, and it was he who made the diagnosis which he presented to his various medical attendants. Here is the full history, written by the patient himself, a man of 66, in the month of April.

"As near as I can remember it is about six years since I first noticed the change in regard to the retaining of my urine; sometimes I would have to get up twice during the night; then in the morning, after using the chamber, I had to repeat a similar action when I got downstairs. Of course, the same thing was taking place during the day also. I once consulted a doctor, who informed me that it was caused by the neck of the bladder growing weak, which was a natural consequence with people who were getting somewhat aged. Previous to six years ago I had the power to hold my urine for a very long time, but I have felt it diminishing more and more every year since. Nevertheless, my health was excellent up till last December, although I was put to much trouble and inconvenience by the complaint. From December last I could feel my health getting bad. I was then compelled to get up five and six times a night to pass urine, and this went on increasing week after week till I am sure I was doing it into the teens of times a night and day also. The desire used to spring upon me very suddenly and forcibly in such a manner that when it wakened me I felt quite startled and alarmed. Up to six months ago, although I had to micturate often, I passed the urine somewhat freely. It was only after I felt some substance making itself evident in the rectum that I commenced to dribble. The substance or lump never protruded much beyond the anus, and always on the right side, and the end of it felt somewhat hard, rounded, and smooth, but it always disappeared after the pressure due to straining was removed. During this time the anus was very much relaxed and the part round about it was extremely soft. Numerous times I have gone into the lavatory with the feeling to use the urinal only, but after I have stood a while I had to make great haste to get into a w.c. because I had lost the power to retain the excrement. For a considerable time before the operation I used to pass the excrement before I passed the urine, which I did not do when these parts were working all right. For some time before you removed the cause of my annoyance, if I put my hands into hot or cold water there came a strong and immediate desire to micturate, which I had to attend to at once if I wanted to keep my shirt dry. A short time before I was sent in to you I caught a severe cold—I tried some patent medicines to cure it, but did not receive much benefit; also had two bottles from our doctor. On March 6th I was in Newcastle and thought it was time to consult a physician about my illness. I was asked a number of questions and requested to take off my coats. The physician then sounded me by tapping my back, and he also applied his stethoscope and told me to inhale slowly—my chest was treated in a similar manner, after which I was asked to lie down on a bench on my chest, when my back was subjected to the same ordeal as before; then over on to my back to undergo the like process.

"I informed him about passing my urine frequently, and about something making itself felt in my rectum. I was told to bend forward and press down, which I did as much as I was able. He informed me that there was not much the matter with me; I was suffering from a little bronchial catarrh, and that I would soon be better. I obtained a prescription which I got made up in Newcastle sufficient to serve two weeks. To my great surprise every day my health commenced to grow worse and worse; my appetite for food had almost gone; my breath was growing offensive; I then got a cough which I thought came from my stomach; the saliva was frothy and had a disagreeable metallic taste—I could not keep my mouth clear of it. I was so ill that I had to send for my home doctor. After he had examined me he came to the conclusion that I was suffering from catarrh of the stomach—at this time I had a horribly dirty tongue. After I had taken two and a half bottles of medicine, which had not done my stomach the least degree of good, and had lost all desire for food—in fact, if I thought about it it created a nauseous feeling, consequently I was getting leaner every day and the number of times I passed urine day and night went on increasing. I made a great mistake in not informing the doctor about the urinary trouble from which I was suffering, but when I told him about it he diagnosed my complaint at once, and told me that my stomach could not possibly get better if I did not get this enlarged gland removed; hence he communicated with you, and as soon as he obtained a suitable reply I was sent on to you."

In another case I was asked to see a farmer 63 years of age as a case of abdominal malignant disease.

When I first met the patient he at once told me that his trouble was indigestion, and he gave a history that he had been perfectly healthy until four weeks previously, when he got cold which caused pain in the left side of the back. The pain soon got well, but it was followed by a fiery heat of the stomach for which he drank a tremendous lot of cold water. After this he began to lose his appetite and felt very ill. There was considerable loss of weight, but this he attributed to the fact that he had not been able to take food. I found the patient a very fresh-looking man, but with a dry red tongue and sourish breath. When he presented his abdomen for examination there was an obvious swelling in the lower part which was the over-distended bladder reaching nearly to the umbilicus. Up to this point he had said nothing about his water, and even on interrogation he would not admit to any urinary trouble until the onset of the present illness. He then found that he had to pass urine very frequently and at once, but for this he blamed the large amount of water which he had taken. Latterly there had been frequent desire to micturate with difficulty in getting the urine away. Per rectum the prostate was found to be very large and was pushed down by the distended bladder. The enlargement was dealt with by the suprapubic operation; the patient made a splendid recovery, and is alive and well ten years afterwards.

In another case of the same kind the man, also a farmer, had been in failing health for some time, but having a great dread of doctors, and especially surgeons, he refused to consult his medical man until about a fortnight previously, when he sent for some medicine to relieve vomiting. When my friend called he found the patient in bed, looking very ill and complaining only of his stomach and vomiting. On examination the bladder was greatly distended; the urine contained albumin, and rectal examination revealed an enlarged prostate. In this case the trouble had evidently been going on insidiously for a very long time and the kidneys were already much involved. The man was relieved by suprapubic cystostomy, but he did not live long and was never sufficiently well for the radical operation for removal of the prostate to be performed.

Another man, 62 years of age, who followed the calling of a commercial traveller, was well aware that his urinary apparatus was not in good working order, but it was only when he began to suffer from nausea and a distaste for food that he sought surgical advice, and he did not connect these symptoms in any way with his old urinary trouble. As a matter of fact the whole of the mischief was due to enlarged prostate, for he made a very satisfactory recovery after a two-stage operation, and now, eleven years afterwards, he is in perfect health and able to carry out his duties as well as at any time during his life.

Quite often the presence of a distended bladder has led to difficulty in diagnosis. A very able practitioner of whom I have the warmest recollection, for he acted as a mentor in my earliest days, and had sufficient confidence to entrust me with surgical work at the very outset of my career, was himself misled in dealing with one of his old patients, a man aged 72, who had been complaining for some time of trouble with his bladder; the real reason for concern, however, was the advent of stomach symptoms with some failure in his cardiac apparatus. In writing about the patient my friend mentioned the symptoms and then concluded, "But what I want to know is *what is* this swelling in the middle line which feels so soft and elastic." As a matter of fact it was a big distended bladder containing 36 oz. of residual urine. In this case also the prostate was removed and the patient made a satisfactory recovery.

Among my treasured possessions is a letter which was sent to one of our surgeons by a well-known physician. I merely mention the standing of this gentleman to show you how easy it is for those trained in clinical observation to be occasionally misled when they are confronted with some condition the like of which is not perhaps frequently brought to their notice. In this case the patient was suffering from nothing worse than a distended bladder, but, as you will see, it was mistaken at first for an obscure tumour. The letter reads as follows:

"July 19th, 1902.

"*Dear Mr.* ——,

"This gentleman came to see me to-day for the first time. He complains of vomiting without pain; quantity of vomit not large. I find a solid, movable growth in the abdomen which curiously resembles in general form and site a uterus pregnant about 5½ months. I have sent him to you for you to consider the advisability of exploring the abdomen. There is a soft systolic bruit at the apex; but the second sound at the pulmonary area is not accented, and the heart action is fairly regular.

"The urine is alkaline (probably from taking 'Carlsbad salts') and contains a very distinct trace of albumin; no sugar.

"Yours very truly."

Forgive me if I allude to another case illustrative of this same point, although, as a matter of fact, the urinary obstruction in this particular example was the result of stricture and not an enlarged prostate.

A man, aged 66, was sent to me by a very discerning doctor friend with a note to this effect: "Do you mind seeing this case for me, an abdominal tumour, not a spleen." The patient only complained of the "lump" in the abdomen. He would not admit that he had any overflow, and certainly his clothes were not in the least damp. He stated that his trouble had commenced four years previously with inflammation of the bladder, but that since then he had not had trouble until he noticed the lump which sent him to his doctor for advice. Fifty years before he had suffered from gonorrhoea. A further examination disclosed a very tight stricture in the deep urethra, and the "tumour" was nothing more than the chronically over-distended bladder.

Intestinal symptoms occasionally overshadow those of obvious urinary origin, as in the case of a man who was sent up with a note stating that he had a history of possible intestinal growth, but that nothing could be felt either on abdominal palpation or rectal examination. None the less the presence of an enlarged prostate had been noted. The fact was that the uncomfortable colic from which this man suffered was simply due to the effects of his enlarged prostate with residual urine.

In a case which I have particular reasons for remembering the patient was a rather older man of 70 years, whose symptoms were entirely rectal. Ineffectual straining and tenesmus, with some prolapse of the mucous membrane, difficulty in voiding faeces, and occasional bleeding, certainly suggested that the cause of his trouble would turn out to be a rectal growth. As a matter of fact, he only suffered from an unusual degree of enlargement of the prostate, and he was completely cured of his rectal discomfort by its removal.

Quite recently I was consulted by a retired sea-captain, a bluff old veteran of 77 years, who came complaining of flatulence and discomfort in the abdomen, and the desire to void wind with pressure; also of some frequency of micturition. He complained that he was always thirsty and had a very dry mouth. In writing about this patient his doctor mentioned that he had a large, round swelling in the abdomen which puzzled him; he stated that it was tense, as if containing fluid, and yet the patient passed water fairly well and had no dribbling. This man turned out to have a distended bladder containing 55 oz. of residual urine. The latter was of low specific gravity and the urea was diminished, but as a result of a two-stage operation he made a satisfactory, though rather tedious, recovery.

Rectal symptoms are sometimes present when the prostatic enlargement is not very marked, and only recently I was rather puzzled by a patient, 60 years of age, who complained of a constant desire to empty the bowel with ineffectual evacuation. In this case the prostate was enlarged and nodular, and, although I feared malignancy, the condition improved very much as the result of treatment, but some months later there was a recurrence with the advent of stomach trouble suggestive of growth, as in the cases I quoted to you at the outset.

A very good example of a patient's misinterpretation of his own symptoms recently came under my observation.

The patient was a man of 54, who assisted his wife in the conduct of a beerhouse. For two or three years he had suffered from discomfort in the abdomen. During this time he was accustomed to drink freely, and he was inclined to blame this over-indulgence for his troubles. Finally he consulted his doctor, who, suspecting stomach trouble, looked at the tongue. This was dirty and thickly coated, but also presented a very obvious papilloma. The man was at once told of the potential danger of this growth, and was sent to hospital for advice as to its treatment. While conducting a leisurely examination for teaching purposes, and with the help of a student, we noticed a very urinous odour. This prompted a more general examination, which at once disclosed a distended bladder with overflow from enlargement of the prostate. When questioned the man admitted that he had been disturbed four or five times each night, but again he blamed his addiction to beer. Latterly his urine had run away without control, and this had caused him to become alarmed.

One of the most important pitfalls of which we must be constantly aware is the class of case in which the patient blames some obvious condition like a hernia or hydrocele for a general failure of health which is really dependent on disorders the result of an enlarged prostate. This is a matter to which I have previously referred,[1] and at that time I ventured to suggest an aphorism which has proved so useful that I would like to recommend it to your notice. It is as follows: "The occurrence of unaccustomed symptoms in chronic conditions is suggestive of some new disease." The following is a case in point.

A gentleman, aged 67, whom I had previously seen on account of some thyroid enlargement, came complaining of a swelling in the right inguinal region, which he had noticed for eight or nine months. He said that latterly it had caused him some pain and discomfort in the lower abdomen and especially after supper. On examination I found an ordinary oblique inguinal hernia. Incidentally, during the course of the examination, the patient mentioned that for a year or more he had noticed increasing trouble with his water—frequency in the mornings, dribbling, and some difficulty in getting the urine away. His appetite and general condition appeared to be unaffected. On rectal examination the prostate was found to be big, rounded, and smooth, certainly twice the normal size, and there was residual urine. In this case prostatectomy was carried out with complete relief of the uncomfortable symptoms which the patient had attributed to his hernia.

The etiology of some of these more general symptoms is quite interesting. Probably they are for the most part due to a certain degree of renal insufficiency and are really an evidence of latent uraemia. Their consideration brings us to the question of so-called "back-pressure," which is so commonly spoken of in connexion with obstruction of the lower urinary passages. It is, I think, an unfortunate expression, because it suggests, at least to my mind—and I have heard it mentioned by others—that the secreted urine goes on accumulating at its usual rate and causes such great pressure in the bladder and kidneys as to give rise to the symptoms which we associate with latent uraemia. As a matter of fact, I hold that such a purely mechanical explanation is untenable, and I believe that what really happens presupposes an amount of intelligence, so to speak, on the part of the renal secretory apparatus. When, for instance, the kidneys discern that the urine does not escape in the ordinary way, there is a holding up, so to speak, of the work of the epithelium, secretion diminishes, and in consequence there is an accumulation of noxious products in the blood. Both these matters would seem to me to be within the scope of easy experimental inquiry, and I commend it to someone with leisure to carry out what would prove, I am sure, a most interesting investigation.

Malignant Prostate.

In connexion with malignant prostate there may be a variety of symptoms which may prove very puzzling. Quite usually they are not directly connected with the urinary organs, not only in the first instance, but even until comparatively late in the development of the malignant disease. Some of the special features to which I would particularly draw attention are complaints of "sciatica" or "lumbago" or "oedema" of one or other lower limb or of the lower part of the abdominal wall, or "enlargement of the groin glands." Pain in the perineum is more ordinary and more suggestive of genito-urinary trouble; it may be the only complaint for a long time, and it may be present when urinary symptoms are entirely absent. It is disconcerting to find to what an advanced degree malignant disease of the prostate may attain before it gives rise to any symptoms whatever. The following is a case about which I was greatly distressed.

A distinguished man whom I saw quite recently was, in his 78th year, in such excellent health that he surprised his friends with his superabundant energy. Only six weeks before I saw him he began to have some day and night frequency of micturition. There was no pain, never any blood in the urine, and at the end of that time he looked in his usual robust health. On rectal examination I was shocked to find a large, hard, infiltrating mass arising in the prostate and extending up into the base of the bladder. On bimanual examination it was obvious that there was a good deal of residual urine, and after this was withdrawn the large mass felt per rectum could be determined bimanually, so great was its size.

In another case what was dubbed "sciatica" was the principal symptom.

The patient was 69 years of age, and, on going into his history, he complained that for several months he had been troubled with wind in the bowels and difficulty in getting them open. Closer inquiry showed that the pain which he called sciatica was really down the inner side of the leg, but it was bad enough to prevent sleep. After examination I wrote to his doctor as follows:

"I have just seen your patient and I find him a most interesting case. I have very little doubt that he has a malignant growth of the prostate—not of the rectum as I was inclined to think from his history. In the situation of the prostate you will find a hard, nodular mass spreading out to the pelvic wall on either side and closely adherent to the bone. You will also notice that the pain in the leg is down the inner side in the distribution of the obturator and not in the sciatic region. I do not quite understand why he should have so much trouble with the bowels, but he admits that it is mostly about the region of the sphincter, which may explain his difficulty. I am sorry to say that it is not a case in which removal can be thought of, and we will have to rely on medicine for his relief."

It is interesting to note that this patient died just about a year after the time that I saw him, and it was only for

the last two months of his life that he had to depend upon the catheter. The pain became very severe, he gradually got weaker, and his end was hastened by some form of oesophageal obstruction.

So-called "lumbago" as well as sciatica appears to be very common at the outset of malignant disease of the prostate, and would more than ever indicate the well-known rule that in both these conditions a rectal examination is essential. Of course, in dealing with the industrial class, an injury is often blamed, and in one such case careful *x*-ray examinations of the pelvis had been made *in search of an old fracture*, but an ordinary rectal examination disclosed a large mass of growth originating in the prostatic area.

Oedema, with swelling of one of the lower limbs, has several times directed my attention to the prostate, malignancy being suspected and usually found.

In one such case, in a man of 64, the only complaint was of swelling of the left leg, which he had noticed for about ten weeks before the time of his visit; there had not been much pain. On *inquiry it turned out that a year previously he had called in his* doctor for what was said to be rheumatism in both feet and one hand. After this illness he was left weak in the bladder and had to be quick in getting to a convenience. At this stage in the recital of his history he said that he blamed the water trouble for bringing on *the swelling of the leg, and I have a note in my* book, between brackets, suggesting that a malignant prostate would be found. He certainly looked a seedy individual, prematurely old and with marked loss of flesh. The affected leg was twice the size of its fellow from lymphatic oedema, and there was a considerable amount of oedema about the genitals and in both groins, while enlarged hard glands were felt in the latter situations. There was no evidence of distension of the bladder, *but on rectal examination the prostate was found to be enlarged,* hard, nodular, and fixed, and there could be no doubt as to its malignant nature.

The following is a somewhat similar case.

A man, aged 76, complained of oedema of the left leg, which he attributed to a blow that he had received three months previously. The leg was found to be almost solid below the knee, and the groin glands on both sides were enlarged and hard. On going further into his history he admitted that for two years there had been some frequency of micturition and that it had recently become very bad by day as well as by night. In this case the bladder was almost up to the umbilicus, and the prostate was slightly enlarged, hard, nodular, and fixed.

In the last two cases the enlargement of the groin glands had not been noticed by the patient and had given rise to no trouble, but it was otherwise in the following case.

A man, aged 70, was sent to me one April at the suggestion of a consulting physician with regard to the advisability of the removal of a mass of glands in the right groin. He gave a history that in the previous October he first noticed swelling of the left leg. For that he had rested in bed for a month as the condition was said to be due to a thrombosis of the internal saphenous. At the time of his visit he told me that he had no urinary trouble, though he did admit that he passed water rather slowly, which he attributed to some weakness of the bladder depending on his age. He did not think that he had lost weight, and certainly looked the big, strong, healthy man that we had been accustomed to see about for many years. There was some oedema and slight discoloration in the region of the right groin. The most prominent gland was of walnut size in the vertical set of femoral lymphatics, but there was a less defined enlargement of the horizontal set, and in the pelvis, above Poupart's ligament, a mass could be felt extending along the brim. On rectal examination the prostate was found to be definitely malignant and was invading the region of the right seminal vesicle. At that time there was no sign of more distant dissemination, but the patient eventually died with multiple secondary deposits all over, though growth in the liver was the most prominent feature.

Recently a public man, who was well known for his municipal activities, was sent to consult me by his doctor, who had discovered him to be suffering from a malignant prostate. The history in this case is very interesting as bearing on this question.

This patient, who was 66 years of age, stated that until two years previously the bowels had been absolutely regular. About that time he began to take grape-fruit, and noticed the onset of constipation and that sometimes the act of defaecation hurt the passage. This trouble, although it only came on at intervals, got steadily worse, and sometimes he had very severe pain lasting for an hour or more after evacuation. About three months previously he began to notice a new pain about the rectum, this time quite independent of evacuation. It came on in attacks and disappeared after a rest. If he could void flatus he got some relief, and was also helped by medical treatment. All this time there was no complaint whatever of urinary symptoms, and even on cross-questioning the patient would not admit that there had been the slightest trouble, the most that could be elucidated was that sometimes he had to get up once during the night, but this only if he had taken a good deal of liquid. He looked absolutely fit and well, and there were no external signs whatever, but on examination the prostate was found to be embedded in growth which was excessively hard and surrounded the lower end of the rectum, leaving a rigid channel which just admitted a finger. It was as if the base of the bladder and the rectum had been embedded in plaster-of-Paris.

Sometimes, and I think more usually, these patients do complain of pain and soreness in the perineum, as in the following case.

A big, handsome man, a farmer, who appeared to be in the pink of condition, gave a history that in March he began to have pain and soreness in the perineum, which troubled him when he attempted to get over fences. Later on it made him unable to ride round his farm. Soon afterwards he began to be troubled with frequent micturition and had to get up two or three times every night. The pain was then worse at night, and he had to lie with his legs apart to get some ease. When I saw him in August he looked quite well, but he was not so vigorous as formerly, and he had to rest at times, instead of pursuing his life of strenuous activity. There was no loss of weight, and he took his food well. The general and external examination was quite negative, but rectal examination disclosed a large, hard, nodular prostate with infiltration and fixation of the whole of the pelvic floor. Eventually this patient had such great urinary difficulty that a suprapubic drain had to be inserted.

In a man of 53 the first symptoms of malignant prostate were stabbing pains down the outer side of the thighs. Soon after this he had an illness following a rigor, and this was succeeded by pain in the perineum and a frequent desire to empty the rectum. Evacuation gave him some little relief, but when I saw him some months afterwards there were no urinary symptoms, in spite of the fact that his prostate was most definitely the source of his trouble.

In some few cases even distant dissemination is present before patients have any symptoms to direct attention to the urinary organs, and I have twice seen patients with secondary malignant glands in the left posterior triangle of the neck who were unaware that the urinary organs were the source of their troubles.

MANAGEMENT OF PROSTATIC CASES.

I will now deal with one or two points of considerable interest in connexion with the "management" of the prostatic case. That old word has always appealed to me, and it seems to epitomize our duty with regard to this particular sort of case very well indeed. One of the most difficult problems for us all is to decide when an operation should be advised. Personally I have no hesitation in saying that I much prefer to deal with patients who have the most trouble, for I have usually found that they have done better than others, and further that they have appreciated the benefits of surgical treatment much more than those patients who have not suffered very much before operation was carried out.

At the outset I would like to emphasize very strongly that the success of the operation for removal of the prostate depends entirely on the relation of the symptoms to the enlargement of the gland, and, if I may put it so, only those patients who suffer because they have an enlarged prostate will be cured by its removal! If operation is performed at an early stage there is a risk of removing the prostate when, as a matter of fact, the symptoms may be due to some other commencing disease. I have, I think, indicated sufficiently the difficulties connected with the very early cases, and I want to tell you the remarkable history of a patient whom I was asked to see by a very alert doctor friend at the time when prostatic surgery was looming large as a result of the pioneer work of Freyer.

The patient, who was suffering from his first attack of retention of urine, was a healthy man, in good general condition. The urine was absolutely normal, and the prostate was only slightly enlarged. As it was his first attack I deemed it wiser to see what could be done by the regular use of the catheter. At that time I only knew that the treatment advised had been effective, and that the patient made a satisfactory recovery; but fifteen years later I was asked to see this same man again. He was then 84 years of age, and he told me that after his previous illness he made a complete recovery, and was very active and well until two years before, when he began to be troubled with some urinary frequency at night-time. These symptoms culminated in an attack of retention which could only be relieved by the use of a silver catheter. The patient looked in very good condition for his years, though the prostate was very large. Again

he made a complete recovery as the result of catheterization, but, of course, the nocturnal frequency continued. Nevertheless, he was so comfortable and so active that he would not agree to any operative intervention.

Many difficulties arise at the other end of the scale—that is to say, when the patient is extremely ill as the result of long-continued urinary obstruction, and it becomes a question as to whether the risks and discomforts of an operation should be urged. In this connexion the story of an old man of 77 who came under my observation some time ago is very instructive. This patient stated that for some years he had suffered from nocturnal frequency with inability to empty the bladder and consequent discomfort. This was followed by a general failure of health, with swelling of the legs, and culminated in an attack of retention which demanded the catheter for its relief. It was at this stage that he was sent to me for an opinion with regard to the advisability of operation. I found a very ill-looking old man with an irregular heart, emphysematous lungs, considerable dyspnoea, and oedema of both legs. The distended bladder was like an abdominal tumour and the prostate was enlarged and suspiciously hard. After examination I wrote to his doctor as follows:

"I am very much obliged to you for sending Mr. M. to see me. Obviously this is not a case for radical operation, and in any event the patient has not very long to live. I strongly suspect that the prostate is malignant, although I confess that the physical signs are not sufficiently definite to entitle one to give a decided opinion on this point.

"I have urged him to allow you to pass a catheter. I would suggest that the instrument should be used some time during the evening, and that you should draw off about two-thirds of the urine. Probably this will give him a much better night, but if it does not do so then it is not worth while persevering with this plan. If I am wrong, and he continues to live after a month or so, then I should be willing to put in a suprapubic drain through a trocar and cannula, but I do not urge this plan as it is attended with considerable risk in one so ill, and I do not care to raise false hopes.

"Some day be sure to let me know, first, if drawing off the urine as I suggest does give him a better night, and second, the date and circumstances of his death.

"By the by, he was extremely anxious to have some medicine, and I think that tincture of digitalis in 15-minim doses thrice daily would probably do some good."

You will understand my surprise when I learned that some five months afterwards this man was so much improved that he was able to resume work on his farm, and had been seen by his doctor on top of a haystack. As a matter of fact, he lived in very good health, and was able to work regularly, for three more years, but at the end of this period he began to fail, and died at 81 and 9 months, without any evidence of urinary infection, in spite of the fact that the catheter had been passed for him by his farmer son some thousands of times.

Operative details are outside the scope of this address, but to make my review complete I would just like to say that I have come to believe that, for the majority of these cases, the operation in two stages is by far the best. I would put it this way: that though I have very often had to regret that I essayed the one-stage operation, I have never regretted the adoption of the two-stage plan, although I quite admit that possibly some of the cases dealt with by two operations might have been successfully tided over the ordeal by one. I speak of two-stage "operations" simply because the circumstances in which I work have taught me that it is much better to make a suprapubic cystotomy rather than endeavour to have preliminary catheter drainage carried out. The latter plan is unsatisfactory with overworked wards and constantly changing house-surgeons and assistants, who never have an opportunity of becoming familiar with the difficulties that may be encountered. The first stage may be simply a suprapubic puncture, using the Morson trocar, but there again I feel satisfied that freer drainage is better, and the results superior if a suprapubic opening of the bladder is made. As a rule this first stage is carried out under general anaesthesia, unless, indeed, the patients are extremely ill, or of the thin and wasted type. The time between the stages varies very much, depending upon the progress of the patient. Usually the interval is not less than two weeks, and, *in fact*, on the rare occasions when I have felt it safe to intervene at a lesser interval, then, I think, without a doubt the operation might have been conducted by the one-stage method. Very often three or four weeks are allowed to elapse, but there is no rule as to the time, and the surgeon must attend on Nature, since it is foolish to intervene as long as the patient is improving, and it is unwise not to take the full advantage of this preliminary relief to the kidneys. The decision as to when the patient is sufficiently well for the second stage does not depend on chemical tests alone, but is mainly judged clinically, and I do not intervene until the patient is cheerful, is sleeping well, has a good appetite with a clean tongue, and presents a thoroughly healthy granulating wound. All these features must be satisfactory or the result is likely to be disappointing. It is in cases in which there is some doubt with regard to the clinical evidence that the examination of the blood urea may be so helpful.

MORTALITY OF PROSTATECTOMY.

For quite a long time I have been accustomed to hear uninformed people rail at the mortality of operations for removal of the prostate, and I have frequently been filled with a sense of shame to hear the opinion expressed that the general mortality in hospitals is something approaching 50 per cent. This is a gross misstatement of the true state of affairs, certainly at the present day. In my own series of cases, which includes the period during which I was trying to learn the technique and the management of the operation, my over-all mortality (that is to say, taking the two-stage with the one-stage operations) was 12 per cent.; for the one-stage operations alone the mortality works out at 19 per cent., and for the two-stage operations just 10 per cent. Most of these operations have been performed in our general hospital, but in keeping the figures I make no distinction between private and public hospital work, and the figures which I have given include the total number of cases, wherever the operation has been conducted. The mortality is steadily diminishing, and is now in the neighbourhood of 5 per cent. This approaches the wonderful figures which were obtained by Freyer, who was able to refer to a mortality of only 3 per cent. in one large series of cases, and those of Young, who in 450 cases had a mortality of just 3.75 per cent.

It is probably those who are so sceptical in regard to the mortality of prostatectomy who speak so scathingly about its advantages. Happily I have been in practice sufficiently long to have been a witness to the utter misery of so many of the victims of prostatic hypertrophy in the old days before the radical operation could be successfully employed; I am therefore able to appreciate the enormous advantages of the methods which are now commonly used. Of course, the period for which these patients enjoy the advantages of the operation is a poor way of assessing the benefits conferred, because in elderly men who require operative treatment the normal expectation of life cannot be long. For instance, in one series of my own patients the average age was 65 years, the youngest being 54, and the oldest 84. But the advantages conferred in some of these cases are incalculable. The following is one of the most striking examples with which I am familiar.

The patient was an old man—particularly old for his age—of 68, who for twelve months had been greatly troubled with nocturnal frequency. The number of times he had to get up gradually increased until he was disturbed not less than a dozen times each night. He was also greatly distressed with frequency during the day, and was only able to pass a very little urine at a time, and that without any force. To add to his troubles he had a severe attack of cystitis, and this was little improved by the irrigation of the bladder which was conscientiously carried out by his doctor. He never suffered from retention. Perhaps this was unfortunate, because quite often the attack of retention which precipitates active treatment is really an intervention of providence which demands that relief which might otherwise be unduly delayed. A mere recital of this man's symptoms can give no idea of the misery of the situation. In the twelve months during which he had suffered his condition had deteriorated so much that he had become a miserable, dirty old man, who neglected himself and his surroundings in a painful way. His condition had made him decrepit and bordering on simplicity, and, as he was a bachelor who lived in lodgings, his relatives were seriously embarrassed because it was found so difficult to get him rooms on account of his dirty habits, soiled beds, etc. Without much prospect, therefore, an operation was undertaken in the hope of so far restoring his condition that he would at least be able to look after himself and cease to be an

annoyance to those about him. The operation was carried out in two stages, and after a rather prolonged convalescence he eventually made a very good recovery. His gain in self-respect was extraordinary, and it was a remarkable thing to see this patient some months afterwards, nicely dressed, with white spats and a smart tie, and an *undoubted concern* for female regard. This happy state continued until four years afterwards, when he died of some condition unassociated with his prostatic troubles, but the details of which I have never been able to ascertain.

The after-history of very many cases is similar, and I merely select a few at random, as I know that many of you, from individual experience, will be able to supply many telling examples. The following is a very striking case.

A man of 60, a hard-working, conscientious artisan, whose symptoms had extended over some years, had evidently suffered so much from renal disability that his working capacity was seriously impaired. The operation had to be carried out in two stages, and his convalescence was attended with considerable anxiety because of symptoms of latent uraemia, but he finally made an excellent recovery, and now, thirteen years afterwards, is fit and well, happy that he can continue his laborious toil as a ship's plater, and willing to carry on in spite of his 73 years, as long as he can find employment.

Another man of the same age had suffered for ten years from urinary trouble, which had increased so much as to interfere very seriously with his ordinary avocation as a commercial traveller. He was very ill, and five weeks had to elapse between the primary operation and the removal of the prostate, and even after that his convalescence was long and tedious, and for a time the prognosis appeared doubtful. However, after a few months his health was restored, and now, thirteen years later, at 73 years of age, he writes me that he is as well as he has ever been in his life, and has recently undertaken renewed responsibility on behalf of his firm.

Another patient, whose history I have already detailed, is so vigorous fourteen years later that at the age of 80 he is still able to walk ten miles without undue fatigue, and has travelled over a large part of the Continent since his operation.

The oldest patient on whom I have ever carried out prostatectomy was 84 years of age and had suffered for long from urinary trouble. The operation was in two stages, and he made an excellent recovery. Unhappily his illness proved so severe a tax on his wife that she succumbed to what I believe was simply the undue exertion associated with her devoted attention to the old gentleman. After his own recovery he was able to take long walks every day, and during the war he went back to his business, from which he had previously retired, and put in long days behind a shop counter. Finally, at 93, the lamp went out, having flickered for some few months, but without any definite cause, the end being like the wearing out of the machinery of life's needful little ways.

Numberless other cases could be quoted, and it is quite usual for patients to speak of "a new lease of life," "a complete restoration to health," and so on.

In some few cases the results have been brilliant in spite of the most unpromising outlook, and I am reminded of a poor fellow who lived in lodgings and who was suffering from diabetes, which for a long time deterred me from attempting the relief which prostatectomy alone offered. He was in such misery from his prostatic condition that he was willing to run any risk, and I am glad to be able to say that the operation was followed by an excellent recovery, which he greatly appreciated.

Sometimes, contrary to all canons, we carry out operations which appear to be contraindicated, and I have in mind two such cases. In both, operation was refused by surgeons who have taken a particular interest in genito-urinary disease. In one case the patient had been condemned to a permanent suprapubic drainage, but at the end of eighteen months he was so dissatisfied that he was willing to undergo any risk, and he made a very satisfactory recovery, being alive and well six years later at the age of 80. Another patient who was refused operation had reached the end of his endurance, and here again, although the circumstances appeared to weigh heavily against his recovery, he did excellently, and is alive and well years afterwards, and classed among my most grateful patients.

RADIUM AND ITS ACTION.*

BY

W. E. DIXON, M.A., M.D., F.R.S.

(From the Pharmacological Laboratory, Cambridge.)

M. BECQUEREL in 1896 noticed that uranium salts affected a photographic plate through an opaque medium, and a few years later similar effects were described for thorium, polonium, and radium. All these metals emit three varieties of rays in different proportions, which are constant for each metal. Radium salts are, however, by far the most radio-active substances known, and have in recent years assumed a great importance in medicine. Indeed, the only practical application of radium at the present time is in medicine, and in this communication radium only will be considered.

Source.

In the early days radium was prepared in Austria from local ores and in France from Portuguese ores; later it was extracted in the United States, and now it is obtained practically entirely from the Belgian Congo. The ores from which it is extracted may be classified as follows:

(1) Pitchblende, an impure uranium oxide found largely in the Belgian Congo. It contains uranium, lead, silica, iron ore, and selenium. The British Radium Corporation deal with pitchblende at Trentwith in Cornwall, but they have extracted probably not more than 10 grams.

(2) Carnotite is a potassium uranyl vanadate, and is obtained from Colorado and Utah.

(3) Autunite or uranite is a calcium uranium phosphate containing lead, and is found mainly in Portugal and Australia.

(4) Betaphite found with mesothorium in Madagascar.

The history of the commercial production of radium is instructive and may be said to have passed through three phases. The first was that of the Austrian monopoly, during which radium was prepared mainly from the pitchblende of Joachimstal in Austria, and to a limited extent from the uranite of Portugal. The price during this phase fluctuated greatly. In 1905 it was marketed at from £5 to £10 per mg.; in 1909–10 at £15 to £27; and in 1912–14 at £36 per mg. The mines in the United States of America were now, however, competing, and as a result of this the price dropped in 1915 to £32 per mg., and in 1916–22 from £24 to £21. At this period the mines in the Belgian Congo were producing and made their presence felt, so that in 1923 the price further dropped to £14, and it now stands at from £10 to £12 per mg. When the mines in the Belgian Congo were in full working the American plant was shut down, perhaps because they could not compete economically with the richer Belgian ores and cheaper labour, though American authorities have stated that the reason was that as much radium had been produced as was needed. Before the Belgians operated, Europe had produced perhaps 60 grams and the United States 160 grams. If we place the total radium in the world at 320 grams we know that America possesses half or more than half of this amount. In 1923 the hospitals in the United States possessed 120 grams.

At the present time the Belgians hold the economic monopoly of radium production. In 1923 their plant produced 4 grams a month, and to the end of 1924 had produced 110 grams. But their sales did not equal their production, since in 1924 they sold only 22 grams of radium, which suggests that either their works were slowing down or they were accumulating stocks. It is necessary to appreciate these conditions in order to be clear that plenty of radium is available to meet all urgent demands provided that the price is forthcoming; it should also be remembered that the radium once produced lasts practically for all time.

The British Government has a Radium Committee now sitting to search for new radium fields in the British Empire, and within the next few years we may confidently anticipate the working of new mines, which, by competition, must inevitably lead to some reduction in price.

* Abstract of a lecture given in Cambridge.

Physical Properties.

The action of radium depends on its physical properties, and these must be referred to briefly. The modern view of the atom is that it is composed of a nucleus carrying a positive charge around which the outer electrons are distributed; these electrons are in a state of constant motion and each carries a negative charge. In a neutral atom the electrons must carry a total charge equal to the charge of the nucleus. The nuclear charge of hydrogen is 1, of helium 2, up to radium with a charge of 88, and uranium with a charge of 92.

The radium atom is remarkable because it breaks up by expelling a single alpha particle, which represents the nucleus of the helium atom, which has a charge of 2; or by shooting off an electron (beta particle). The expulsion of the alpha particle lowers the nuclear charge of the atom of radium by two units, and a substance referred to as emanation is produced which is composed of a gas, niton, allied to argon; further expulsion of alpha and beta particles produces a series of radio-active elements known as radium A, B, C, D, E, and F, until ultimately lead is formed, which is non-radio-active. No protons (hydrogen nuclei) are emitted, but only helium nuclei and electrons. Radium salts are thus being continually transformed into other metals, and it has been estimated that about half the radium will be transformed in 1,700 years. The activity of radium salts is measured by the discharge of a gold-leaf electroscope. When radium is used in mass for treatment of the patient the gamma rays only are employed, the alpha and beta particles being screened off—as, for example, by means of 1 cm. of lead. Emanation collected in capillary tubes has the same effect as radium, but its activity is soon lost and ceases in a few days.

Radium, then, has three known types of radiation: alpha particles of helium, which are readily stopped by paper or the skin; beta particles or electrons, which are stopped by 2 or 3 mm. of aluminium; and gamma rays, a type of *x* ray, but four times harder than anything which can be produced by bulbs; the gamma rays are produced by the energy liberated in the expulsion of the alpha and beta particles. Radium emanation, or radon, is usually collected in capillary tubes and retains its radio-active properties for a few days only. Substances like lead-foil, or even common salt, placed in the neighbourhood of radium become coated and can be similarly used for superficial applications. Sodium chloride so treated is sometimes dissolved in water and used for injection purposes. The only radio-active substance present in the body is potassium, and the gamma rays which it emits are of greater penetrating power than those emitted by radium.

Action.

General Effects.—The rays emitted from radium exert a pronounced action on the animal body, and if the dose is sufficient may cause death. For example, if 50 or 60 mg. of the bromide are placed within 8 or 10 cm. of a mouse-cage for two days the animals die within three weeks. Guinea-pigs and rabbits after a similar exposure also die, though only after several weeks. The symptoms are loss of hair, ulcerations on the skin, especially if the rays have not been screened, nervous symptoms such as paralysis, sexual impotence, and ultimately coma. After death the central nervous system appears inflamed, the whole vascular system is dilated, the capillaries are injected, and the nerve cells in sections show signs of degeneration, though this is not necessarily a primary effect of the rays, but may be the result of capillary haemorrhages. Larger animals do not exhibit these effects in the same degree.

Local Action.—This is of great importance in surgery, because radium is largely used to destroy tissues; for general purposes emanations are to be preferred to the metal, not only on account of convenience, but of economy and safety. The various tissues in the body are not affected equally by radium; the most susceptible is the lymphatic system, including the spleen, the gonads, and, though to a smaller extent, the central nervous system. Thus the testes of small animals atrophy, the epithelium degenerates, and spermatozoa are not formed. The effect on the ovaries is shown by the production of artificial menopause. These results are all associated with inflammatory signs, including marked dilatation of the capillaries. Developing eggs and embryos are very susceptible to the rays; bacteria, on the other hand, are affected only feebly, though the mobile forms are killed more easily than others. One explanation of the selective action of radium on certain tissues is the fact that it decomposes lecithin, and it is just those tissues which are rich in lecithin that are affected most. It has also been suggested with good evidence that the degenerative changes seen after radium are due to the toxic action of this decomposed lecithin. It may almost be accepted on broad lines that the susceptibility of tissues to radium varies with their rate of growth. Tumours are certainly more susceptible than normal tissues, rapidly growing tumours more than sluggish or benign tumours, lymphosarcoma more than carcinoma. Hence it is easy to understand that tubes of emanation buried in cancerous tissue cause degeneration of the cells and reduction in the size of the growth. In the treatment of deep-seated tumours injury to the intervening superficial tissues must be minimized as far as possible by screening off the alpha and beta rays, the alpha rays in particular having the most intense superficial effect. One other point is worth noting: the gamma rays increase the activity of the autolytic ferments, thus facilitating the absorption of dead cells. Many local conditions are now treated successfully with radium—such as rodent ulcer, lupus vulgaris, and naevi.

Systemic Action.—But besides this local action for which the surgeon uses radium, it is sometimes administered internally to produce systemic effects. Minute amounts of a salt of radium taken by the mouth are very rapidly absorbed, permeate the whole body, and are excreted as emanation and radiation by the lungs, and to a smaller extent by the urine. It is more usual, however, if a general effect is required, to take emanation either by the mouth or as an inhalation. No doubt the best method of administration for systemic effects is to use a water charged with emanation. A usual amount is half a pint daily containing 1.5 to 2 millicuries per litre. After the administration of very large amounts of emanation such as may be given as an inhalation to animals, general depression, marked dyspnoea, and death have been observed; the characteristic changes after death are widespread hyperaemia and changes in the nerve cells of the central nervous system. The indications for the employment of radium for its systemic action are still ill defined. The most successful use to which it has been put is to relieve pain in fibrous arthritis, sciatica, and tabes. The explanation of this action is suggested by the frequency with which the use of this kind of treatment is followed by a general "flare-up" of the affected tissue: indeed, the drinking of radium water may start an acute attack in any part subject to chronic inflammation. The known action of radium in producing inflammatory changes even in normal tissues is exaggerated in the case of tissues which already show chronic inflammatory effects. In other words, we are dealing with a kind of shock treatment somewhat analogous to protein-shock therapy. In chronic gout the effect is often of the same nature; in the gouty the employment of radium may initiate an acute attack, though general improvement is said to follow after some weeks. In this instance the treatment is purely palliative, since the uric acid in the blood is not affected.

Radium has met with a small degree of success in certain blood diseases. It certainly influences both the bone marrow and spleen: after the prolonged use of small doses in normal people the red blood corpuscles are said to be increased as well as the leucocytes in the peripheral circulation. Large doses have the opposite effect. There is nothing remarkable in this action; other substances have a like effect. Radium also increases the coagulability of the blood to a decided degree. In the leukaemias the local application of radium over the lymphatic glands and spleen has caused temporary improvement. It is well known that both *x* rays and radium diminish the leucocytes and the size of the spleen in leukaemia, though no permanent improvement in the disease occurs with either. It is interesting to note that the serum obtained from patients recently subjected to *x* rays, when injected into lymphocytic patients, induces a reaction.

Radium has been used also in many other diseases, such as glycosuria, arterio-sclerosis, and high blood pressure, but the beneficial results sometimes accredited to the treatment are altogether unconvincing. So far as the evidence exists, then, the action of radium is due mainly to its effect on blood vessels and perhaps on lecithin. Thus on the skin the capillaries dilate, leucocytes migrate, and later extravasations of fluid occur. The same type of action may occur in any tissue in the body, and the effect is especially marked on chronically inflamed tissues. The changes noted in the central nervous system always begin in the blood vessels, and the ne[illegible] is probably secondary, though it must [illegible] the central nervous system contains a large amount of lecithin.

THE USE OF THE CAUTERY IN OPERATIONS UPON THE STOMACH.

BY

CHARLES A. PANNETT, M.D., F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; SURGEON TO ST. MARY'S HOSPITAL.

GASTRIC operations have often to be undertaken in ill-nourished and debilitated individuals for whom the conservation of every drop of blood is a prime consideration; more than this, such operations can only be performed with

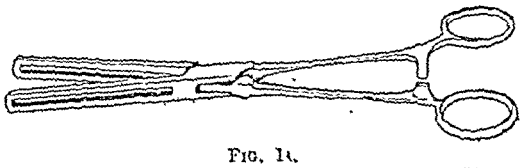

FIG. 1A.

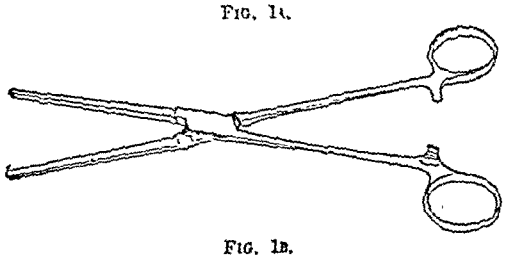

FIG. 1B.

any prospect of success when this primary condition of the preservation of the patient's blood is complied with. The ordinary haemostatic clamps will enable this to be done, but there are many occasions where it is not possible to gain sufficient room to apply the clamps and allow of easy suturing. This is nearly always the case with a high gastrectomy or a duodeno-antrectomy, and in such circumstances a considerable loss of blood is apt to take place from the cut margins of the duodenum, stomach, or jejunum. To avoid this some surgeons have used a Paquelin cautery for section of the viscera, but the method is objectionable because of the rather wide margin of burnt and damaged tissue that is left. This necessitates a considerable in-turn at the anastomotic site, and a mass of scar tissue remains.

There are two essential conditions for making the use of the cautery for this purpose satisfactory: (1) the circulation should be controlled whilst the cautery is being used, because otherwise more heat is necessary owing to the cooling action of the blood stream; (2) the heating effect should be limited to within a very few millimetres of the margin. Both these conditions are fulfilled by the use of the clamps shown in Figs. 1A and 1B. The clamps are light and narrow and yet thick. They control the circulation, and the mass of metal conducts away the heat and distributes it so that the cauterizing effect is not produced beyond the clamp itself. The clamps are used as follows:

Gastro-jejunostomy.—The jejunum and posterior wall of the stomach, having been displayed and held in apposition by two traction sutures, are fixed together by the seroserous stitch (Fig. 2). A small incision into each viscus is then made close to the suture line for the introduction of one blade of the fenestrated clamp. The blades of the clamp are closed and the visceral wall divided with the cautery through the slot. When the clamps are removed the small vessels divided in the edge of the incision will be found to have been sealed. Now and then a single isolated larger vessel will bleed, but this is easily controlled by a ligature, and the subsequent suturing is as easy and unembarrassed by haemorrhage as in the cadaver.

Billroth I.—In performing this operation the stomach just proximal to the pylorus has often been divided between strong clamps to facilitate access to the posterior aspect of the stomach or duodenum. The sites for division of the duodenum and stomach having been selected the viscera are sutured along this line in their posterior walls. Two clamps are then placed upon the stomach and the organ divided with the cautery distal to them, as in Fig. 3. The clamp on the lesser curvature is removed, and this part of the stomach closed with suture. The duodenum, after clamping, is divided in the same way and united to the remaining part of the cut lumen of the stomach. The fenestrated clamp is not necessary for this operation.

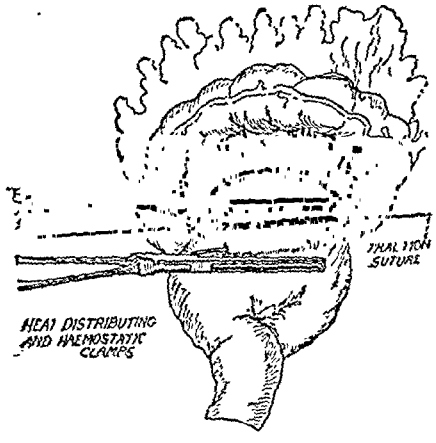

FIG. 2.

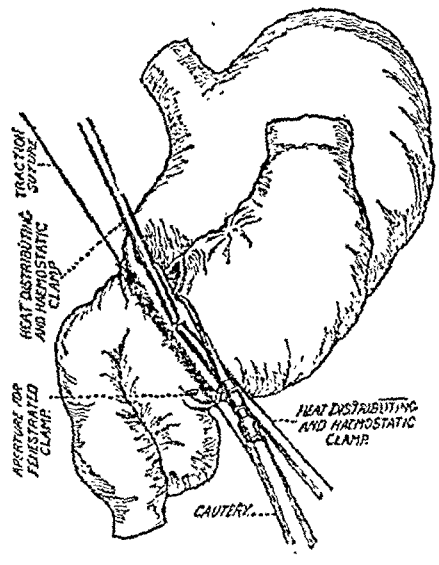

FIG. 3.

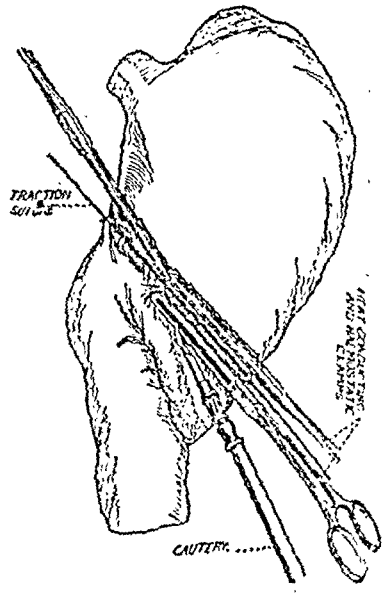

FIG. 4.

The Polya type of operation is performed in a similar way, two simple clamps being used for the stomach and a fenestrated clamp for the jejunum (Figs. 3 and 4).

The cautery technique has enabled me to undertake operations upon patients whom otherwise I should have considered unfit to stand a gastrectomy. It is, I believe, an important factor of safety in this difficult branch of surgery. It not only has this advantage, but the absence of ordinary clamps during the actual suturing makes this part of the operation easier to carry out, and thus leads to a saving of time.

PERICARDITIC PSEUDO-CIRRHOSIS OF THE LIVER, OR PICK'S DISEASE.

BY

A. WILSON GILL, M.D.ED., M.R.C.P.,

SENIOR HONORARY ASSISTANT PHYSICIAN, NORTH STAFFORDSHIRE ROYAL INFIRMARY;

AND

T. CRAIG, M.B., CH.B.GLAS.,

HOUSE-PHYSICIAN TO THE HOSPITAL.

THE association in young people of enlarged liver with recurring ascites and chronic adherent pericardium is not a very common condition. The earliest reported case was probably the one reported by Van Deen in 1846, but a more complete description was given in 1896 by Pick, and the symptom-complex is often described as Pick's disease, or Pick's pericarditic pseudo-cirrhosis of the liver. Most modern textbooks of medicine do no more than merely mention this disease, but many monographs have been written on it, and most of the references in this paper are abstracted from a lengthy monograph by Kelly[1] printed in the *American Journal of the Medical Sciences*.

The disease presents many problems yet unsolved, notably the true cause of the condition and the relationship it bears to two other diseases—namely, Concato's disease on the one hand, and "Zuckergussleber," observed by Budd in 1852, and graphically named "sugar-iced liver" by Curschmann in 1884, on the other.

In Pick's disease chronic adherent pericardium occurs in association with chronic venous congestion of the liver, and while few adhesions are found in the peritoneum, the surface of the liver, though often opaque, does not show the dense layer of fibrous tissue common in sugar-iced liver. Rolleston,[2] in fact, declares that there is a very definite microscopic distinction in these two conditions. The fibrous tissue increase in Pick's disease is deposited under the capsule, whereas in Curschmann's disease the fibrous overgrowth is outside the capsule. The same author also states that "if peritoneal adhesions are advanced, the condition ceases to be Pick's pseudo-cirrhosis of pericarditic origin," and belongs to that of chronic universal perihepatitis associated with adherent pericardium. Kelly also has some difficulty in classifying the three conditions which clinically and pathologically seem to merge into one another, and considers that they are best grouped under the wider term of "polyserositis" or "polyrrhomenitis."

The important factor in all is the occurrence of chronic inflammatory changes in various serous surfaces, associated with a great tendency to ascites; this demands frequent tapping, although the intervals between each paracentesis may be far apart. In a case described by Rumpf the ascites was tapped 301 times, and in Osler's[3] case of a child 121 times. This factor alone is of importance in distinguishing the disease from the true multilobular cirrhosis, which rarely requires tapping more than a few occasions before death ends the disease. In other respects the etiology is different from cirrhosis chiefly in respect of the age incidence—polyserositis tending to attack young people—and in the absence of the usual irritants—for example, alcohol. Pick recognized this difference when he called his disease "pseudo-cirrhosis," but the name is not a bad one, as when the cases are seen first the diagnosis of cirrhosis is often made, especially as the adherent pericardium is sometimes difficult to diagnose during life. When the disease occurs in young people an alternative diagnosis of tuberculous peritonitis is often made, and in this connexion Rolleston and others[4] consider that the tubercle bacillus may play a part in the causation.

The pathological findings in polyserositis are fairly constant and have been reported many times. In fully developed cases changes are found in all the serous surfaces, although the changes in the pericardium and round the liver are the most obvious and most constant. Dense adhesions often calcified, are found in the pericardium, valvular disease is often present, and the heart enlarged. Adhesions occur in both pleural cavities, the right side being usually more advanced than the left. Enlarged spleen with perisplenitis and chronic peritonitis occur. The liver is usually enlarged, and shows the usual nutmeg character of chronic venous congestion. Microscopically, the liver shows irregular areas of fibrosis, but generally the amount of fibrosis is scanty and may be absent in considerable areas (Rolleston).

Most observers have been puzzled, in view of the pathological findings, to explain the recurring ascites, and many theories have been advanced. The frequent occurrence of dense adhesions in the right pleural cavity was believed by Weinberg, in 1887, to cause angulation and distortion of the inferior vena cava and hepatic veins, and Eisenmenger supported this theory in 1900. Neither Kelly nor Rolleston favours this view. Harris (1895) considered that the ascites was the result of a peculiar form of chronic peritonitis, while others believe that the heart condition is responsible. Against this latter view is the usual absence of œdema of the legs, although in some cases a transient œdema occurs at the beginning of the illness. Kelly sums up the three opinions thus: (1) That the ascites is due to changes in the liver, the result of long-standing congestion. (2) That the ascites is due primarily to the chronic peritonitis. (3) That the ascites is due to the combined action of these factors.

The actual exciting cause of the condition is still obscure. In many cases there is no history of antecedent illness. In others there is some indication of an acute onset attacking one serous membrane—for example, the disease may follow a definite attack of pleurisy or an attack of pericarditis. It has occasionally followed certain acute and infectious illnesses, notably rheumatism, syphilis, typhoid fever, and malaria. Both Kelly and Rolleston lay great stress on antecedent rheumatism. Others believe that the tubercle bacillus is an important factor even in the absence of definite evidence of tuberculosis, and some authors actually state that all cases of chronic adhesive pericarditis are tuberculous in nature. Certainly it is a fact that some of these cases ultimately die of tuberculosis. Picchini (1901) distinguished four groups of cases.

1. Cases where the origin of the disease can be determined—that is, the first serous membrane affected.
2. Cases where the origin may be determined, but in which the first examination of the patient reveals some affection already of several serous membranes, although they manifest no clinical signs.
3. Cases where the history reveals that from the beginning several serous membranes have been affected.
4. Cases where it cannot be determined whether the disease began with one or more serous membranes.

Mention has already been made of the prevalence of the disease in youth, and the following figures from Kelly's paper demonstrate this fully. Of 39 cases, 21 occurred in males, 18 in females: 3 were under 10 years of age, 13 were between 11 and 20 years, 3 were between 21 and 30 years, 5 were between 31 and 40 years, 11 were between 41 and 50 years, and 4 were between 51 and 54 years.

The following case exhibits most of the clinical features common to such cases—namely, the early age incidence, the absence of antecedent disease, the gradual onset, the occurrence of ascites and enlarged liver, in association with evidence of cardiac disease, presumably adherent pericardium.

A boy, aged 14½ years, was admitted to the North Staffordshire Royal Infirmary on June 26th, 1928, because of ascites and throbbing of the neck.

History.—In June, 1927, he began to notice an increasing size of the abdomen, which caused him to have some slight shortness of breath on exertion, so that he no longer could challenge boys to run races or play football with vigour. Closer questioning elicited the fact that pulsation in the neck on the right side had been noticed by his parents for the previous two years, but no importance was placed by them on this observation as they looked upon him as a perfectly fit boy who had played football for the school for two seasons. He left school at Christmas, 1927, beginning work as an apprentice engineer in January, 1928, and working steadily until June 5th. On this date various apprentices were referred to the factory surgeon for examination as to fitness, when this boy was rejected and advised to secure medical advice. For the purpose of this examination he cycled a distance of three miles, and on arrival was obviously short of breath. He then consulted Dr. A. Gilchrist of Burslem, who diagnosed "Concato's disease" and referred him to the Royal Infirmary.

Previous Illnesses.—He was born at full time, was bottle-fed, and was not looked upon as a delicate child. When 2 months old he had a slight attack of bronchitis or broncho-pneumonia lasting two weeks, from which he made a full recovery and had no complications. At the age of 7 years he developed measles, and again there were no ill effects. He has suffered from occasional colds in the head and slight rheumatic pains in the wrists in winter, but there is no history of tonsillitis, chorea, or acute rheumatism, and no record of pleurisy. At the age of 12 he slipped off a 4-foot wall to the ground and landed with his knee pressed against his chest. He was at once short of breath, and had pains across the chest which lasted three hours, after which he felt quite well and returned to school the next day. Since measles at the age of 7 he has not missed school attendance.

The family history is not important, the parents being alive and healthy, three brothers alive all healthy, and no deaths in the family have occurred. There is no tuberculous history on either side.

Symptoms on Admission.—Fullness of the abdomen and throbbing of the neck were the obvious symptoms. Occasional pain across the chest and in the left shoulder and slight indigestion were further admitted. No cough was complained of, and no record could be [illegible] of swelling of the legs.

Condition [illegible]—*His height* was 5 ft. 1¼ in., *his* weight 7 [illegible] ot look a robust boy, the complexion being somewhat sallow, but there was no cyanosis and no obvious shortness of breath. Undue venous pulsation was noticed in the neck, especially on the right side. No clubbing of the finger-nails was present and no oedema of the legs. The abdomen was distended by free fluid, the circumference at the umbilicus being 32 inches. The free edge of the liver could be felt three inches below the costal margin, the liver itself feeling smooth but firm. Scanty pubic hair was present, but there was no hair in the axillae. A few small glands were present in the axillae. The teeth were good, the tonsils not enlarged, tongue slightly coated. On July 8th paracentesis was performed, 96 ounces of a clear straw-coloured fluid being withdrawn. Culture was negative, and very few lymphocytes were found on staining. Injection into a guinea-pig had no ill effects on the latter. After withdrawal the lower pole of the spleen was just palpable. No enlarged glands or tuberculous masses could be felt in the abdomen. The chest was hyper-resonant in the upper lobes. The lungs expanded freely. The breath sounds throughout were harsh vesicular in type. No adventitious sounds were heard except a fine friction over the splenic area. The chest was *x*-rayed on June 26th by Dr. J. Bromley of Stoke-on-Trent, who reported as follows:

"Both diaphragms are raised, doubtless due to the amount of free fluid in the abdomen. There is no marked increase in the extent of the hilum shadow and no impaired air entry into the chest." The urine was free from albumin and sugar, and the urea concentration test was normal. Blood urea did not exceed 13.5 mg. per 100 c.cm. The Wassermann reaction of the blood was negative. A fractional test meal revealed no abnormal features. The levulose tolerance test increased the amount of sugar in the blood from 0.12 to 0.22 per cent., and no sugar was passed in the urine. The blood count on June 26th showed red blood cells 3,700,000, white blood cells 11,500, haemoglobin 75 per cent. Differential count: Polymorphs 80 per cent., lymphocytes 18 per cent., eosinophils 1 per cent. No abnormal cells were found.

Condition of the Heart.—A distinct fullness was observed over the precordium. The apex pulsation was scarcely visible, and there was no indrawing of the interspaces. No thrill was felt on palpation, and the positions of the heart borders and of the apex beat itself were difficult to define by percussion, owing to the hyper-resonant note of the lungs. Careful percussion, however, seemed to locate the apex beat in the fifth interspace about half an inch outside the nipple line. There was a definite epigastric pulsation visible. Auscultation revealed a curious high-pitched musical squeak, which was audible at one time and absent at another. The character of this bruit was very peculiar. On certain occasions it was heard all over the precordium and over the left scapula; at other times it was absent behind. Sometimes it was more marked at rest, sometimes only after exercise. It was at times loudest during deep expiration, and occasionally it would disappear altogether for long spells, during which intervals no valvular disease was apparent. The timing of this sound also varied. Usually it coincided with the closure of the aortic valves, at other times it occurred during ventricular systole. It seemed to have its origin outside the heart itself, and probably depended upon some adhesion between the pericardium and neighbouring structures. The systolic blood pressure was consistently low, the average being 112 mm. of mercury. The pulse rate averaged 90 per minute, and the exercise tolerance test was normal. The electrocardiogram taken both before and after paracentesis showed the constant inversion of T-wave in leads ii and iii. No particular ventricular preponderance was present.

Progress.—After paracentesis on July 8th the boy's health seemed to suffer and a progressive slight loss of weight occurred for a week or two afterwards. With iodide of iron internally and iodoform inunction to the abdomen his health began to improve and he gained weight—some of this increase being due no doubt to a slight return of the ascites. The chest was again *x*-rayed by Dr. J. Bromley on August 10th, his report being: "There appeared to be some enlargement of the ventricular shadow to the right, while in the left hilum a distinct bulge is seen, suggesting an enlarged clump of glands. Both diaphragms moved well at this examination." A further blood count was performed on August 22nd, which showed the improvement which had occurred—namely: red blood cells 5,500,000, white blood cells 16,500, haemoglobin 85 per cent. Differential count: Polymorphs 78 per cent., transitionals and mononuclears 4 per cent., lymphocytes 16 per cent., eosinophils 1 per cent., basophils 1 per cent. No abnormal red cells were found.

He was discharged on September 1st in good condition, and when re-examined on November 4th, 1928, he looked plump and well, but ascites had largely accumulated again and a very slight oedema of the legs was found. His weight was 8 st. 3 lb., and there was no apparent shortness of breath or distress on exertion. Further paracentesis will shortly be necessary.

INOPERABLE CARCINOMA OF THE BREAST TREATED WITH RADIUM.

BY

ROY WARD, M.B., B.S.,

ASSISTANT MEDICAL SUPERINTENDENT, THE RADIUM INSTITUTE, LONDON.

In considering the radium treatment of carcinoma of the breast it must be remembered that both external applicators and needles are employed. The apparatus must be screened in such fashion as to cut off the beta rays, which are harmful to the tissues, and permit the gamma radiation to pass; 2 mm. of lead is recommended for external plaques when prolonged exposures are contemplated. A compound known as "Columbia wax" is most useful when treating a large surface area. For slow-growing tumours needles with walls of 0.5 mm. of platinum are recommended; these vary in active length from 1 to 5 cm., and contain 0.5 mg. of radium element to each centimetre. More recently tiny needles known as "seeds" have been found to be useful in some cases. The most convenient seed is one containing 2 millicuries of radon and screened through 0.5 mm. of platinum or gold. In cases of encephaloid character, where the growth is extremely rapid and very vascular, more powerful needles, screened through 1 mm. of silver, are often of great value.

REVIEW OF CASES.

An attempt has been made to ascertain the fate of the 633 patients suffering from breast carcinoma who have been treated at the Radium Institute during the last ten years. A study of these cases has not only made it possible to form an opinion as to the value of radium therapy in hopeless cases, but from the information obtained certain principles can be formulated for the treatment of patients in whom the disease is less advanced. In the series under review, which does not include patients who received prophylactic treatment, it was found that in every case the disease had extended to tissues outside the breast itself.

Summary of Results.—Of 510 cases (1918–25), 112 were alive at the end of three years=22 per cent. Of 405 cases (1918–23), 51 were alive at the end of five years=12.6 per cent. Of 82 cases (1918), 5 were alive at the end of ten years=6.1 per cent. All those patients on whom a recent report has not been received have been regarded as having died at the date of the last report.

CONCLUSIONS.

Not only are the results given above very encouraging, but a large number of patients (about 40 per cent.) showed marked temporary benefit, even though they succumbed within three years of treatment. Most of the cases were too advanced to offer any hope of cure, but much was done to relieve suffering and control the progress of the disease. Distressing symptoms were often alleviated, and in many cases life was prolonged for a considerable number of years. Ulcerations were healed or prevented, thereby relieving the patient of a good deal of pain. Cutaneous nodules disappeared, while large swellings became smaller and less fixed, often regressing to such an extent that only a residual thickening could be felt. Relief was often obtained even in cases where there was marked lymphatic obstruction with oedema of the arm, the limb becoming less swollen and more movable.

It must be remembered that the above series represents pioneer work in the radium treatment of breast cancer. A review of cases treated during the past three years promises to show more favourable results. This is due to the fact that patients are being sent for treatment at a less advanced stage, and also to the advances made in technique during the last three years.

SOME GENERAL CONSIDERATIONS IN THE TREATMENT OF CARCINOMA OF THE BREAST.

Cases may be classified into three groups: early operable, late operable, and inoperable.

Early Operable.—Although the logical conclusion is that radium therapy is competent by itself to deal with very early cases of carcinoma of the breast, it has yet to be shown that radium treatment alone can give as good results as operation. When the growth is still confined to the breast, and there are no palpable axillary glands, operation has given good results. Statistics published by the Ministry of Health show that operation will keep 75 per cent. alive for ten years. In this class of case radium treatment must not be regarded as a substitute for operation at present, but much may be accomplished by using radium as an adjunct to surgery. Striking results have been obtained by Mr. Geoffrey Keynes in cases of carcinoma which are technically operable; but at present his cases are too recent to justify any positive deductions, and it remains to be seen whether the ultimate results of the treatment are as good as those of surgery.

Late Operable.—This is a group of cases which requires careful consideration. The disease is no longer confined to the breast itself, but is still considered technically operable by all but the most conservative surgeons. Of the 633 patients treated at the Radium Institute between 1918 and 1923 74 per cent. were recurrent cases following amputation of the breast. Of these cases 290 (46 per cent.) had palpable supraclavicular glands. The fact that a large proportion of these metastases became evident within six months from the date of operation shows that a much more conservative judgement is required in deciding whether a breast cancer is operable. This is a most important point. Of these "late operable" patients few are cured, and some are made worse by operation. An area containing cancer cells is opened up by unsuccessful surgery, and this acts as a stimulus to the growth. When a recurrence appears the axilla soon becomes filled with a fixed mass of disease. There is much scarring and fibrous tissue formation, the blood supply is poor, and there is little or no surrounding healthy tissue. Subsequent radium treatment is undertaken at a great disadvantage, and with less chance of success than if radium had been employed without any previous operation.

Inoperable.—Inoperable and recurrent cases, in which a radical operation is out of the question, have been considered above. This class of case is often greatly benefited by radium treatment. Some surgeons remove as much of the growth as possible, and then pack the wound with radium. Experience has shown that this is frequently a disastrous procedure. Metastases in the supraclavicular region should be treated with radium alone, since the results following excision do not encourage operative intervention.

The Primary Growth.

The treatment should be such as to cause the growth to disappear with little or no tissue necrosis. The amount of radium required, the intensity of the dose, the filtration, and the time of exposure vary to some extent with the nature and extent of the neoplasm. Scirrhous growths require needles of low content heavily screened and left *in situ* for a comparatively long time, about a week. When an ulcer exists the needles should be introduced into the healthy tissue in the immediate vicinity of the growth. Isolated subcutaneous nodules are best treated with platinum or gold seeds containing radon. Retrogression usually occurs much more slowly in schirrous growths than in highly cellular tumours. The reason for this probably lies in the comparative avascularity of schirrous lesions. Large doses of radium, especially if lightly screened, may cause necrosis and sloughing. Encephaloid tumours, apart from being more cellular, are more vascular. Rapidly growing tumours are more susceptible to irradiation, and respond more dramatically than the schirrous growths. They require a large dose for a comparatively short time, three or four days, and the needles need not be so heavily screened. Severe systemic disturbance often occurs in the course of the treatment of such cases, owing probably to the absorption of products of disintegration, and a very remarkable degree of shrinkage is often seen at the end of a fortnight or three weeks after irradiation. The treatment of the primary growth should be supplemented by the application of an external plaque, but it is inadvisable to employ this when the needles are *in situ*.

The Associated Lymphatic Areas.

Just as in the surgical treatment of carcinoma of the breast it is not enough to do a local amputation, so in the radium treatment it is insufficient to treat only the primary growth, even if there are no palpable glands. The treatment should be directed on the same lines, by a thorough irradiation of the chest, concentrating on the associated lymphatic areas, and those areas in which metastases and recurrences are most likely to appear. (See Table I.) Mr. Geoffrey Keynes in his technique irradiates these areas by inserting radium needles of low content in the axilla, above and below the clavicle, and at the sternal ends of the first three or four intercostal spaces. Mr. Sampson Handley treats these areas by burying very powerful needles in similar situations for much shorter periods, and if the case is operable he performs a complete amputation of the breast at the same time. Mr. Handley believes that breast cancer when it comes to operation is already an intrathoracic disease. Although the needles inserted in these areas have prevented metastases occurring in Mr. Keynes's series the rational treatment appears to be to treat the chest more thoroughly. The area to be irradiated must be a wide one, and is best treated by the external application of large quantities of radium over a comparatively long period, concentrating on these particular areas. Apart

from the fact that a more thorough irradiation of the mediastinum is obtained there is no risk of necrosis of cartilage or bone, which may occur even with needles of low content buried in the near vicinity of these tissues. Heavy filtration is necessary—2 mm. of lead or its equivalent should be employed. Large doses must be given at a minimum distance of 15 mm. from the skin surface.

External application of radium has been discouraged as unsuccessful mainly by those who have not had sufficient quantities at their disposal, for inadequate doses of radium have been responsible for many so-called failures. External irradiation, however, has a very definite place in radium therapy, although it must be remembered that the skin is very sensitive and is easily damaged by rays which are insufficiently screened. In this country Mr. Stanford Cade has shown that the skin can be subjected to enormous doses in the "collar treatment" of secondary cervical glands by using heavily screened radium applied to a mould of "Columbia wax." The superficial layers of the skin peel off, but the skin heals rapidly, leaving a soft pigmented scarred surface, but no contraction. This effect on the skin must be caused by the continuous gamma radiation, which has this effect only when employed for long periods.

Pre- and Post-operative Radium Therapy.

This is still a matter for a great deal of investigation. It has been impossible to form any opinion as to its value from the study of cases treated at the Radium Institute, but there are reasons for supposing that many recurrences might be prevented if pre- and post-operative irradiation were more often employed. Statistics have been published to show that in patients who have had pre- and post-operative irradiation the outlook is better than in cases treated by surgical means alone. It has been erroneously stated that pre-operative radium treatment causes delay in healing, and affects the tissues in such a way as to make operation more difficult. Microscopical sections of irradiated tumours tend to show that it is unnecessary to postpone subsequent operation for more than a fortnight.

There is no doubt that recurrences appearing after prophylactic irradiation are very refractory to further irradiation. Similarly it is found that a second treatment of any neoplasm is less effective than the primary treatment. For this reason the first treatment should always be as thorough and vigorous as possible. If a second treatment is necessary the dose must be relatively smaller.

THE EFFECTS OF ANAESTHESIA, OPERATION, AND CERTAIN OTHER FACTORS ON GLYCAEMIA.

A PRELIMINARY INVESTIGATION.

BY

ERIC MEKIE, M.B., F.R.C.S.ED., AND HUGH MILLER, M.B., F.R.C.S.ED.

(From the Department of Clinical Surgery, Edinburgh University.)

THE administration of glucose is an accepted procedure in the treatment of post-operative shock. The value of this treatment is now questioned, since it has been reported that hyperglycaemia occurs after operation. This investigation was undertaken to determine the effect upon the blood sugar of a surgical operation carried out under routine conditions, and to ascertain the factors which influenced any changes observed. The action of the administration of rectal and subcutaneous glucose salines was studied.

Investigation Carried Out.

Observations were made on patients who had been admitted to the wards and who all had the routine preparation, except in those cases admitted as emergencies for immediate operation. The last meal was on the evening before operation, but the patient received a cup of tea early the next morning. Purging of the patient was restricted to a small dose of castor oil on the day previous to, and an enema on, the morning of operation.

In most cases the blood sugar was estimated before operation, and on many occasions after the commencement of the operation. In several cases the blood sugar was estimated again some days after operation under conditions similar to those which obtained on the day of operation, but, of course, without the mental strain which operation entails. In addition to the investigation of the blood sugar, patients have had a record of the pulse rate taken at corresponding intervals of time, and these readings have been graphed along with the blood sugar curve. In all cases we have noted: (1) The history of the illness, attention being especially directed to any points which might be suggestive of sepsis or of diabetes. (2) The general condition of the patient, especially any degree of shock or constitutional disturbance. (3) The nature and duration of the anaesthetic, together with the time and dose of any drugs administered.

Method.

Samples of venous blood were taken from the patients at various times. The estimations of the blood sugar were made by means of the Benedict picric method,[1] which allows of some delay between the obtaining of the sample and the carrying out of the estimation. The estimations which involved the comparison of fine degrees of colour were undertaken by one of us (E. M.) to avoid possible individual variation. Seventy-seven cases have been investigated and have been analysed.

Pre-operative Level of the Blood Sugar.

The average level of the blood sugar in a fasting healthy adult when estimated by this method is 120 mg. per cent.[2] In all our cases we examined the blood sugar before operation to enable us to establish a standard for each patient, and we found that the pre-operative level of the blood sugar varied considerably. The highest level which we have observed has been 227 mg. per cent., while the lowest level in our series was 84 mg. per cent.; the average reading obtained from the 73 cases analysed was found to be 124.3 mg. per cent. According to Pierce and Scott,[3] who used MacLean's method of blood sugar estimation, the normal level of the blood sugar in a healthy adult lies between 95 and 99 mg. per cent. In view of these figures and the figures of Levi[4] and Miss Potter[5] (to which reference will subsequently be made), it seems to be a fair conclusion that there is a phase of hyperglycaemia before operation. An analysis of our cases suggests that the condition from which the patient was suffering had a considerable influence upon the level of the blood sugar.

We made a special analysis of those cases where the pre-operative level of the blood sugar was above the recognized maximum in normal people (160 mg. per cent.).[6] We found that out of the 57 cases operated on under general anaesthesia 13 were above this high level of glycaemia, and averaged 184 mg. per cent. Of these 13 cases 9 were admitted as emergency cases—3 being duodenal perforations and 4 acute appendicitis.

The effect of various conditions is also borne out by Table I. We conclude that three factors are demonstrated to bear influence on the glycaemia: (1) acute infection, (2) surgical shock, (3) peritoneal irritation. Nervousness is a factor in pre-operative hyperglycaemia, since such

TABLE I.—*Pre-operative Blood Sugar in Various Conditions.*

Condition.	Cases.	Average Pre-operative Blood Sugar.
		mg. per cent.
Hernia and hydrocele	9	118.1
Acute appendicitis localized—that is, acute infection	12	137.0

General peritoneal infection: perforated duodenal ulcer (4), appendicitis	5	185.4
Various cases in which there was a well-marked focus of chronic sepsis	7	114.1
Various cases in which no obvious sepsis was noted	17	122.3

operations as those for hernia and hydrocele, which we have found to be unassociated with pre-operative apprehension by the patients, have not a high blood sugar content.

Variation in Blood Sugar during Operation under General Anaesthesia.

Ethyl chloride, chloroform, and ether were the anaesthetics employed during routine operations. In only a few of our cases did the patients have an all-chloroform or all-ether anaesthesia. We have considered all these cases together because the reaction observed does not appear to depend on which of the above drugs was used. Fifty-seven cases were given a general anaesthetic, and had blood sugar curves prepared which show the relationship between the pre- and post-operative levels. Of these, 48 showed a rise in the blood sugar content, while 9 showed a fall. Over the whole of this series of cases the average rise in the blood sugar content as compared with the pre-operative

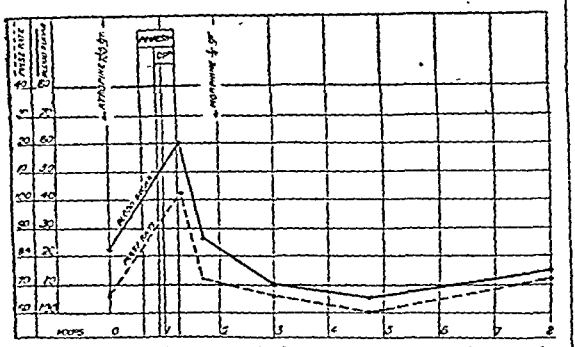

FIG. 1.—Graph illustrating blood sugar curve in patient operated on under general anaesthesia. Note similarity between pulse rate and blood sugar curves.

level was 44.96 mg. per cent., the greatest increase observed being 165 mg. per cent. and the greatest decrease 39 mg. per cent.

The observations showed that in the majority of the cases the reading of the blood sugar at the end of the operation and the administration of the anaesthetic was the highest obtained. The subsequent estimations approximated more closely to the pre-operative level. In no case, however, did we find any evidence of a period of hypoglycaemia, although we made systematic observations up to eight hours after the operation, and in some cases over a longer period—up to thirty-six hours. Investigations after eight hours, however, were considered to be vitiated by the number of complicating factors—for example, food, sedatives, restlessness, etc. Fig. 1 illustrates the type of curve obtained.

Post-operative Glycaemia.

In order to enable us to form an opinion of the post-operative variations of the blood sugar content, we com-

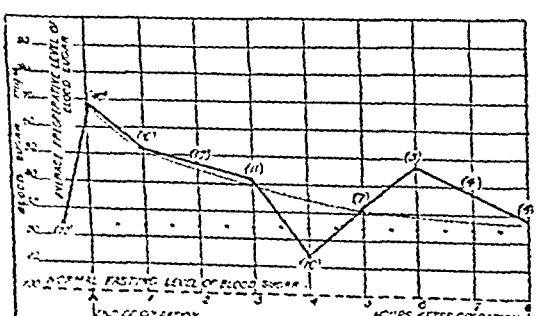

FIG. 2.—Composite graph. Points represent averages of readings taken each hour. Dotted line indicates probable course of blood sugar.—cf. Fig. 1.

puted the accompanying composite graph (Fig. 2), since it is apparent that specimens of blood cannot be withdrawn from patients after surgical operations with the frequency and regularity which strict scientific investigation of this problem requires. The points on the graph represent the average of the readings taken at certain periods after operation. Thus, in 16 cases the average reading of the blood sugar one hour after operation was 28 mg. over the pre-operative level, while in 17 cases the average reading two hours after operation was 23 mg. over this level. For the first three hours of the post-operative period the points gave a regular curve, but thereafter the figures showed some variation. We believe this to be due to (1) the fewer readings on which the graph at these points was based, (2) the increasing number of factors which altered the condition of the patient. We suggest, however, that the dotted curve indicates the course which the blood sugar will follow after an operation under general anaesthesia in the average case.

Relationship between Duration of Anaesthesia and Hyperglycaemia.

We have found evidence that there is a relationship between the absolute rise of the blood sugar and the duration of the anaesthesia. Table II shows the figures

TABLE II.—*Relationship of Duration of Anaesthesia to the Rise of the Blood Sugar Content.*

Duration of Anaesthesia.	Rise in Blood Sugar (mg. %).	No. of Cases.
Up to 30 minutes	27	12
30–45 minutes	41	23
45–60 ,, ...	62	13
60–75 ,, ...	58	10
90 minutes	(38)	(1)
110 ,, ...	(47)	(1)

obtained from a series of 58 of our cases, and suggests that the more prolonged the anaesthesia the greater will be the increase of the post-operative over the pre-operative reading. Twelve cases have been investigated with a view to

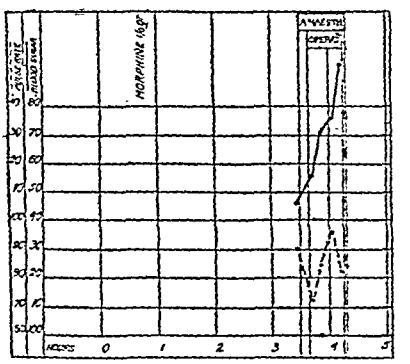

FIG. 3.—Graph illustrating progressive rise in blood sugar during anaesthesia and operation.

ascertaining the changes which occur during the operation, and have nearly all shown a progressive rise in the blood sugar content. It has been noted in one or two cases where the anaesthetic had been administered for some time before the actual operation started that the rise in this period was very similar to the rise in the second period during which the operation was being actually performed. One typical graph to illustrate these points is given (Fig. 3). We did not find that the post-operative duration of the hyperglycaemia depended on the duration of the anaesthesia.

The Duration of the Hyperglycaemia.—The question of the severity of the operation and the duration of the anaesthesia with their relation to the blood sugar curve was brought specially into prominence by the statement of Levi[1] that the duration of the period of hyperglycaemia depends on these factors. We cannot confirm this statement. In our series of cases we found eight cases in which the hyperglycaemia was sustained for a longer period than our composite graph showed to be normal, but we have failed to find any common causal factor. The operations included severe surgical intervention such as amputation

of the breast and gastro-enterostomy, and also simpler operations like appendicectomy and herniotomy. We further investigated the question of the absolute rise in the glycaemia in association with the *severity* of the operation. We were unable to find any difference in the average levels of the hyperglycaemia in the cases of the more severe operations and those less severe, always provided that the operations were of approximately the same average duration.

Hyperglycaemia after Abdominal Operations.—We found that there was a greater rise in the blood sugar content after those operations where the peritoneum had been irritated than in those cases in which the peritoneum had not. Table III shows this fact.

TABLE III.—*Relationship between the Degree of Hyperglycaemia and the Type of Operation.*

Type of Operation.	Average Duration. (minutes).	Rise in Blood Sugar (mg. %).	No. of Cases.
Abdominal...	46	50.3	38
Extra-abdominal	54	39.35	17

Pulse Rate and Glycaemia.—We have been struck by the fact that the blood sugar curve and the pulse rate curve are very similar. This has held true not only for what we have come to regard as normal curves, but even where the curves were atypical. (See Figs. 1 and 4.)

Fall in Blood Sugar During Operation.—In 9 cases (15.8 per cent.) of the 57 cases analysed we observed a fall in the blood sugar content during operation instead of the usual rise. We believe that such a fall is associated in most cases with a high pre-operative level in the blood sugar content. It is to be noted that 6 of the 9 patients showing a fall in the blood sugar after operation are in the group of 13 cases with high pre-operative blood sugar levels (over 160) to which reference has already been made.

Cases Operated on with Spinal Anaesthesia.

Observations were made on 6 cases in which spinal anaesthesia was employed. We found the changes in the blood sugar content were not in conformity with those in which the patient had a general anaesthesia for operations of the same duration of time. The method of producing spinal anaesthesia was as follows: One hour before operation preliminary narcosis in the form of "twilight sleep" was induced by giving 1/4 grain of morphine and 1/100 grain of hyoscine. In one case where there was much excitement a further dose of 1/6 grain of morphine and 1/200 grain of hyoscine was given a quarter of an hour before operation. The spinal injection consisted of tropacocaine 0.075 gram in 3 cases, stovaine 1 c.cm. of 10 per cent. solution in 3 cases.

TABLE IV.—*Blood Sugar Changes in Cases of Spinal Anaesthesia.*

* Patient shocked; given subcutaneous salines; was very nervous before operation.

† This patient was given a double dose of narcotics.

‡ Patient received post-operative treatment with glucose and insulin.

The degree of glycaemia was estimated just before the administration of the narcotic and at varying periods thereafter. Table IV shows the results obtained. From the readings it will be observed that there was a rise of the blood sugar during the operation in 4 cases and a fall in 2 cases—the average being a rise of 13.8 mg. per cent. This figure is very considerably lower than the corresponding one for operations performed under general anaesthesia. (Fig. 4.)

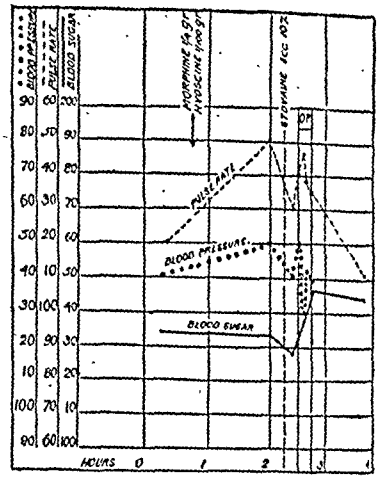

FIG. 4.—Graph illustrating effects of spinal anaesthesia.

Effect of Morphine and Hyoscine given before Operation.

The effect of hyoscine and morphine is also shown in Table IV. In 5 of these cases there was an average rise of 9 mg. per cent. In one case (No. 2) there was a distinct fall in the blood sugar, but we noted in this case that a very considerable degree of nervousness was allayed by the administration of the narcotic. We have also investigated the effect of morphine (1/6 grain) given before a general anaesthetic, and we have found an average rise of 19 mg. per cent. within one and a half hours. We would, however, point out that this small dose of morphine is not sufficient to control the excitement which is initially present and which is increased by the taking of the patient to the theatre, where the second sample has invariably been taken. The action of morphine is twofold; it is generally accepted that it raises the blood sugar, but we believe that in so far as it allays nervousness it may cause a lowering of the blood sugar.

Administration of Glucose after Operation.

In our series of cases we have had 6 patients in whom the post-operative shock was sufficiently severe to call for the administration of a subcutaneous glucose saline, which has been our previous routine treatment, 500 to 900 c.cm. of 6 per cent. glucose being given. We have been interested to note that the blood sugar, just before the administration of this glucose, in 2 cases was over 200 mg. per cent., while the average level was 174 mg. per cent. in the 6 cases. In another case glucose was given subcutaneously during operation, and at the end of the operation the blood sugar stood at 224 mg. per cent., but the patient was so shocked that an immediate blood transfusion was ordered. There is no doubt that glucose administered subcutaneously causes a rise in the blood sugar content; the average blood sugar content rose in our cases within one and a half hours by 68 mg. per cent.

Glucose enemata, which were given both as a routine measure in cases where stomach operations had been carried out and as the treatment for minor degrees of shock, gave much more variable results. We found that in a series of 7 cases the blood sugar level before giving the first rectal glucose was high (average 153 mg. per cent.). The readings after administration of enemata varied: in 3 cases there was a distinct rise, in 4 cases a distinct fall, and in one case little change. The highest increase observed was 33 mg., while the greatest decrease noted was 49 mg.

Levi[4] has reported 10 cases in which he has investigated the blood sugar after operation. In all of these cases there has been noted a rise in the level of the sugar content,

and he has found that the maximum rise occurs in the first reading taken after the operation, after which there is a gradual fall. Some of his samples were taken as long as forty-eight or seventy-two hours after the operation. In this series of cases the average pre-operative level was 133.4 mg. per cent., and the average rise in the reading, in the seven cases investigated, within half an hour of the completion of the operation was 29 mg. per cent.

Levi states that the duration of the rise depended on the duration of the anaesthetic and the severity of the operation. In our opinion there is not sufficient regard paid by this investigator to the effect of post-operative treatment as affecting the figures on which he bases these conclusions, and our own observations do not confirm them.

D. Potter,[5] working in the gynaecological wards in Edinburgh Royal Infirmary on the chemical changes in the blood following on operation, showed that there was a distinct rise in the blood sugar content. The average initial reading which she obtained was 125.3 mg. per cent. (but it should be noted that these cases all received a small dose of morphine before the blood sample was taken), while the average rise in the sugar content was 35.3 mg. per cent. D. Potter comes to the conclusion that the hyperglycaemia is more dependent on the ether administered than on the excitement or asphyxia due to the operation.

Mackay[7] has recently made two communications on this subject. He groups his cases according to whether the anaesthesia was of thirty or sixty minutes' minimum duration. The average figures which he obtained are quoted, since they show close similarity to our own results. In twenty cases with shorter anaesthesia the average pre-operative reading was 106 mg. per cent., and the average rise at the end of the operation 43 mg. per cent. In the group with longer anaesthesia the corresponding figures were 112 mg. and 104 mg. per cent.

Clinical Application.

We desire to draw attention to two indications in the treatment of cases which result from our investigations:

1. In the preparation of a patient for operation nervousness should be allayed. We have not sufficient data on which to found definite rules, but sedatives seem to be indicated.

2. The post-operative phase is accompanied by a raised blood sugar content, and therefore there is no necessity for the administration of glucose.

Conclusions.

1. Four factors at least predispose to a high pre-operative level of the blood sugar—namely, acute infection, peritoneal irritation, shock, and nervousness.

2. Following operations under general anaesthesia there is usually an increase in the blood sugar content, but there is never a hypoglycaemia.

3. The maximum rise is seen immediately after operation, and from this point there is a fall to the pre-operative level, which is approximately reached in eight hours.

4. There is a close relationship between the absolute rise of the blood sugar and the duration of the anaesthesia.

5. In cases of post-operative shock the blood sugar content is high.

6. In spinal anaesthesia there is evidence of only a small rise in the blood sugar content.

7. Absorption from rectal glucose saline does not lead to any constant change in the blood sugar readings.

We have to acknowledge our indebtedness to Professor John Fraser and Mr. George Chene for permission to carry out this investigation of their cases, and to Professor Murray Lyon, in whose laboratory the chemical estimations were made. The expenses for this study were borne by a grant from the Moray Fund.

MEDICAL, SURGICAL, OBSTETRICAL.

PRESSURE NEURITIS OF THE DEEP PALMAR BRANCH OF THE ULNAR NERVE.

I WAS most interested in reading, in the *Journal* of January 19th (p. 98), Dr. Wilfred Harris's communication under the above heading and his account of two cases, since during the past two years I have met with no fewer than four similar cases. Also, as with Dr. Harris, I was unable to find an adequate description of the condition in the literature of nerve injuries or neuritis. In two of my cases the exciting cause was fairly obvious—both were young men and keen motor cyclists. In both cases the right hand was affected, and, as with one of Dr. Harris's cases, the undue pressure had been brought about by gripping the handle-bar termination too tightly in the effort to control vibration. In the two other cases—one a lady aged 63 (right hand) and the other a medical man aged 57 (left hand)—it was difficult to determine with certainty the exciting cause. At the same time, the lesion, of sudden onset, was so clearly limited to the deep branch of the ulnar nerve that it was scarcely possible to imagine a cause other than trauma by pressure—especially after one had seen the two previous cases. The paralysis was limited entirely to abduction and adduction of the three outer fingers, adduction of the little finger, and adduction of the thumb. There was no loss of sensation in the ulnar area, while abduction and opposition of the thumb and little finger were unaffected. In the first case pressure might have been caused by the use of a garden trowel, and in the second by holding too tightly the handle-bar cork of an ordinary bicycle. Although the pressure was applied intermittently over a long period, the actual onset of the paresis was sudden in all four cases, occurring during the course of the night or one evening.

C. WORSTER-DROUGHT, M.D., M.R.C.P.,
Physician to the Metropolitan Hospital and to the West End Hospital for Nervous Diseases.

CEREBRAL ANGIOSPASM.

I RECENTLY had under my care an interesting case of fugitive paralysis of the arm, presumably due to spasm of a cerebral arteriole. Since I find very little on the subject in the textbooks, or in contemporary medical literature, I venture to place it on record.

My patient was a medical practitioner, aged 71, of fairly good general health and careful dietetic habits. There was no history of syphilis. The blood pressure before the attack was 170 mm. maximum, 90 mm. minimum. At the termination of a two months' holiday in Europe, during which he may have eaten a little more than his usual restricted dietary, he was gathering figs with the head thrown back at an acute angle. He suddenly became aware that he had lost all movement in the left arm from the shoulder down to the fingers. He said he felt a little "funny" on the right side of his head when this happened, but neither the tongue nor the corresponding leg was affected. Movement began to return in the hand in the course of a quarter of an hour, and the paralysis had quite cleared up an hour or so later, leaving only a large anaesthetic patch over the deltoid muscle. This persisted for ten days or so, when it also cleared up, but an area of dysaesthesia (numbness and tingling) appeared on the left side of the occipital region. Six weeks later no trace remained. The patient mentioned that he had been suffering from precordial pain and, more recently, shortness of breath on effort, especially after eating. For the last six years he had noticed an intermittent limp on both sides, pointing to partial obstruction of the tibial arteries. The heart sounds were normal. There was nothing abnormal in the urine.

For several years past he has from time to time had scotomata in one or other eye. Sometimes the area obliterated was so extensive as to amount to blindness in one eye, but more often it was merely a large black or greyish patch in the field of vision. This lasted from a few minutes to half an hour, and then gradually cleared up; nothing abnormal was seen between whiles with the ophthalmoscope. This occurred mostly when travelling—that is to say, when his digestive organs had not had fair play owing to changes in his habits of life. This ephemeral occurrence was also no doubt due to spasm of a retinal arteriole.

O. K. Williamson[1] has recorded three cases of transient hemiplegia in elderly subjects, which he attributes to arterial spasm not lasting long enough to cause necrosis of

[1] *Journal of the Medical Association of South Africa*, May 25th, 1923.

of the breast and gastro-enterostomy, and also simpler operations like appendicectomy and herniotomy. We further investigated the question of the absolute rise in the glycaemia in association with the *severity* of the operation. We were unable to find any difference in the average levels of the hyperglycaemia in the cases of the more severe operations and those less severe, always provided that the operations were of approximately the same average duration.

Hyperglycaemia after Abdominal Operations.—We found that there was a greater rise in the blood sugar content after those operations where the peritoneum had been irritated than in those cases in which the peritoneum had not. Table III shows this fact.

TABLE III.—*Relationship between the Degree of Hyperglycaemia and the Type of Operation.*

Type of Operation.	Average Duration. (minutes).	Rise in Blood Sugar (mg. %).	No. of Cases.
Abdominal...	46	59.3	38
Extra-abdominal	54	39.35	17

Pulse Rate and Glycaemia.—We have been struck by the fact that the blood sugar curve and the pulse rate curve are very similar. This has held true not only for what we have come to regard as normal curves, but even where the curves were atypical. (See Figs. 1 and 4.)

Fall in Blood Sugar During Operation.—In 9 cases (15.8 per cent.) of the 57 cases analysed we observed a fall in the blood sugar content during operation instead of the usual rise. We believe that such a fall is associated in most cases with a high pre-operative level in the blood sugar content. It is to be noted that 6 of the 9 patients showing a fall in the blood sugar after operation are in the group of 13 cases with high pre-operative blood sugar levels (over 160) to which reference has already been made.

Cases Operated on with Spinal Anaesthesia.

Observations were made on 6 cases in which spinal anaesthesia was employed. We found the changes in the blood sugar content were not in conformity with those in which the patient had a general anaesthesia for operations of the same duration of time. The method of producing spinal anaesthesia was as follows: One hour before operation preliminary narcosis in the form of "twilight sleep" was induced by giving 1/4 grain of morphine and 1/100 grain of hyoscine. In one case where there was much excitement a further dose of 1/6 grain of morphine and 1/200 grain of hyoscine was given a quarter of an hour before operation. The spinal injection consisted of tropacocaine 0.075 gram in 3 cases, stovaine 1 c.cm. of 10 per cent. solution in 3 cases.

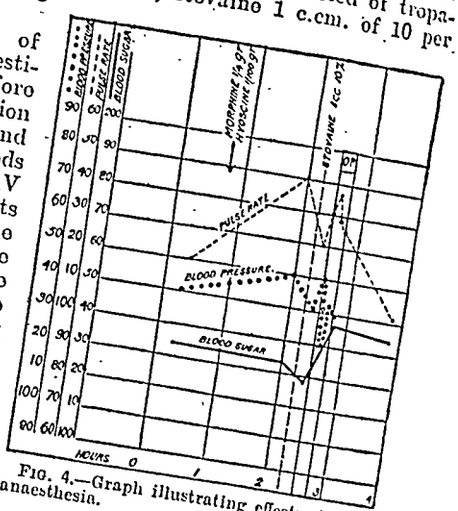

FIG. 4.—Graph illustrating effects of spinal anaesthesia.

The degree of hyperglycaemia was estimated just before the administration of the narcotic and at varying periods thereafter. Table IV shows the results obtained. From the readings it will be observed that there was a rise of the blood sugar during the operation in 4 cases and a fall in 2 cases—the average being a rise of 13.8 mg. per cent. This figure is very considerably lower than the corresponding one for operations performed under general anaesthesia. (Fig. 4.)

Effect of Morphine and Hyoscine given before Operation.

The effect of hyoscine and morphine is also shown in Table IV. In 5 of these cases there was an average rise of 9 mg. per cent. In one case (No. 2) there was a distinct fall in the blood sugar, but we noted in this case that a very considerable degree of nervousness was allayed by the administration of the narcotic. We have also investigated the effect of morphine (1/6 grain) given before a general anaesthetic, and we have found an average rise of 19 mg. per cent. within one and a half hours. We would, however, point out that this small dose of morphine is not sufficient to control the excitement which is initially present and which is increased by the taking of the patient to the theatre, where the second sample has invariably been taken. The action of morphine is twofold; it is generally accepted that it raises the blood sugar, but we believe that in so far as it allays nervousness it may cause a lowering of the blood sugar.

Administration of Glucose after Operation.

In our series of cases we have had 6 patients in whom the post-operative shock was sufficiently severe to call for the administration of a subcutaneous glucose saline, which has been our previous routine treatment, 500 to 900 c.cm. of 6 per cent. glucose being given. We have been interested to note that the blood sugar, just before the administration of this glucose, in 2 cases was over 200 mg. per cent., while the average level was 174 mg. per cent. in the 6 cases. In another case glucose was given subcutaneously during operation, and at the end of the operation the blood sugar stood at 224 mg. per cent., but the patient was so shocked that an immediate blood transfusion was ordered. There is no doubt that glucose administered subcutaneously causes a rise in the blood sugar content; the average blood sugar content rose in our cases within one and a half hours by 68 mg. per cent.

Glucose enemata, which were given both as a routine measure in cases where stomach operations had been carried out and as the treatment for minor degrees of shock, gave much more variable results. We found that in a series of 7 cases the blood sugar level before giving the first rectal glucose was high (average 153 mg. per cent.). The readings after administration of enemata varied: in 4 cases there was a distinct rise, in 4 cases a distinct fall, and in one case little change. The highest increase observed was 33 mg., while the greatest decrease noted was 49 mg.

Levi[4] has reported 10 cases in which he has investigated the blood sugar after operation. In all of these cases there has been noted a rise in the level of the sugar content,

TABLE IV.—*Blood Sugar Changes in Cases of Spinal Anaesthesia.*

No. of Case and Nature.	Blood Sugar before Narcotic Injection.	Blood Sugar after Narcotic before Injection of Spinal Anaesthetic.	Blood Sugar after Spinal Anaesthetic before Operation.	Blood Sugar after Operation.	Subsequent Blood Sugar Estimation.	Rise of Blood Sugar during Operation only.

55. Amputation of leg	85	96	—	80	111 3 hrs. later	
58. Diabetic gangrene amputation‡	83	103	—	116	110 4 hrs. later	−16
59. Tuberculous knee; amputation through thigh	100	119	—	108	— 140 3 hrs. later	13 −11

* Patient shocked; given subcutaneous salines; was very nervous before operation.
† This patient was given a double dose of narcotics.
‡ Patient received post-operative treatment with glucose and insulin.

and he has found that the maximum rise occurs in the first reading taken after the operation, after which there is a gradual fall. Some of his samples were taken as long as forty-eight or seventy-two hours after the operation. In this series of cases the average pre-operative level was 133.4 mg. per cent., and the average rise in the reading, in the seven cases investigated, within half an hour of the completion of the operation was 29 mg. per cent.

Levi states that the duration of the rise depended on the duration of the anaesthetic and the severity of the operation. In our opinion there is not sufficient regard paid by this investigator to the effect of post-operative treatment as affecting the figures on which he bases these conclusions, and our own observations do not confirm them.

D. Potter,[5] working in the gynaecological wards in Edinburgh Royal Infirmary on the chemical changes in the blood following on operation, showed that there was a distinct rise in the blood sugar content. The average initial reading which she obtained was 125.3 mg. per cent. (but it should be noted that these cases all received a small dose of morphine before the blood sample was taken), while the average rise in the sugar content was 35.3 mg. per cent. D. Potter comes to the conclusion that the hyperglycaemia is more dependent on the ether administered than on the excitement or asphyxia due to the operation.

Mackay[7] has recently made two communications on this subject. He groups his cases according to whether the anaesthesia was of thirty or sixty minutes' minimum duration. The average figures which he obtained are quoted, since they show close similarity to our own results. In twenty cases with shorter anaesthesia the average pre-operative reading was 106 mg. per cent., and the average rise at the end of the operation 43 mg. per cent. In the group with longer anaesthesia the corresponding figures were 112 mg. and 104 mg. per cent.

Clinical Application.

We desire to draw attention to two indications in the treatment of cases which result from our investigations:

1. In the preparation of a patient for operation nervousness should be allayed. We have not sufficient data on which to found definite rules, but sedatives seem to be indicated.

2. The post-operative phase is accompanied by a raised blood sugar content, and therefore there is no necessity for the administration of glucose.

Conclusions.

1. Four factors at least predispose to a high pre-operative level of the blood sugar—namely, acute infection, peritoneal irritation, shock, and nervousness.

2. Following operations under general anaesthesia there is usually an increase in the blood sugar content, but there is never a hypoglycaemia.

3. The maximum rise is seen immediately after operation, and from this point there is a fall to the pre-operative level, which is approximately reached in eight hours.

4. There is a close relationship between the absolute rise of the blood sugar and the duration of the anaesthesia.

5. In cases of post-operative shock the blood sugar content is high.

6. In spinal anaesthesia there is evidence of only a small rise in the blood sugar content.

7. Absorption from rectal glucose salines does not lead to any constant change in the blood sugar readings.

We have to acknowledge our indebtedness to Professor John Fraser and Mr. George Chiene for permission to carry out this investigation of their cases, and to Professor Murray Lyon, in whose laboratory the chemical estimations were made. The expenses for this study were borne by a grant from the Moray Fund.

CEREBRAL ANGIOSPASM.

I RECENTLY had under my care an interesting case of fugitive paralysis of the arm, presumably due to spasm of a cerebral arteriole. Since I find very little on the subject in the textbooks, or in contemporary medical literature, I venture to place it on record.

My patient was a medical practitioner, aged 71, of fairly good general health and careful dietetic habits. There was no history of syphilis. The blood pressure before the attack was 170 mm. maximum, 90 mm. minimum. At the termination of a two months' holiday in Europe, during which he may have eaten a little more than his usual restricted dietary, he was gathering figs with the head thrown back at an acute angle. He suddenly became aware that he had lost all movement in the left arm from the shoulder down to the fingers. He said he felt a little "funny" on the right side of his head when this happened, but neither the tongue nor the corresponding leg was affected. Movement began to return in the hand in the course of a quarter of an hour, and the paralysis had quite cleared up an hour or so later, leaving only a large anaesthetic patch over the deltoid muscle. This persisted for ten days or so, when it also cleared up, but an area of dysaesthesia (numbness and tingling) appeared on the left side of the occipital region. Six weeks later no trace remained. The patient mentioned that he had been suffering from precordial pain and, more recently, shortness of breath on effort, especially after eating. For the last six years he had noticed an intermittent limp on both sides, pointing to partial obstruction of the tibial arteries. The heart sounds were normal. There was nothing abnormal in the urine.

For several years past he has from time to time had scotomata in one or other eye. Sometimes the area obliterated was so extensive as to amount to blindness in one eye, but more often it was merely a large black or greyish patch in the field of vision. This lasted from a few minutes to half an hour, and then gradually cleared up; nothing abnormal was seen between whiles with the ophthalmoscope. This occurred mostly when travelling—that is to say, when his digestive organs had not had fair play owing to changes in his habits of life. This ephemeral occurrence was also no doubt due to spasm of a retinal arteriole.

O. K. Williamson[1] has recorded three cases of transient hemiplegia in elderly subjects, which he attributes to arterial spasm not lasting long enough to cause necrosis of

[1] *Journal of the Medical Association of South Africa*, May 26th, 1923.

the cerebral area involved. In such cases, if cerebral haemorrhage and embolism can be excluded, there remains only arterial spasm to account for the fugitive paralysis. We are familiar with angiospasm in "dead finger" which lasts for half an hour or more, but since it does not entail any permanently injurious consequences it does not attract much attention. A more impressive instance of spasm is ophthalmic migraine, an essentially spasmodic affection in which the patient may develop hemianopsia or even aphasia, which disappears without leaving any trace.

One feature of these cases of arterial spasm is that the symptoms, instead of progressing from bad to worse, are very variable, more or less "undulating," so that it is very difficult to formulate even an approximate prognosis. If the spasm subsides in good time there may be no permanent disability, but prolonged spasm of an arteriole, damaged but capable under ordinary conditions of giving passage to the blood, is apt to set up necrobiosis of brain tissue or brain softening.

Apart from arterial spasm, or possibly with it, there may be perturbations of blood pressure, and I gather that more or less sudden variations of the latter may pave the way to brain softening far more than mere hyperpiesis. A sudden fall of pressure consequent upon free blood-letting may have a very detrimental effect on the cerebral circulation, causing ischaemia of a territory already inadequately irrigated. According to Chavany and Berard-Dellestable[1] the harmful effects of these sudden variations of pressure only obtain in respect of arteries that are the seat of disease, so that one never meets with cerebral symptoms consequent upon the sudden fall of pressure associated with colloidoclasic shock (intravenous injection of metallic colloids). Nevertheless it is presumably advisable to abstain from "shock" treatment in elderly people.

In cases of diabetic coma or threatening ictus one is very prone to resort to free blood-letting, but while this may not be inopportune in presence of cerebral haemorrhage with high blood pressure, it is quite otherwise in cases of spasm or thrombosis in the production of which hyperpiesis plays an insignificant part.

Syphilis is, of course, a frequent—possibly the most frequent—cause of impediment to cerebral circulation, and the possibility of this origin must always be borne in mind.

A. S. GUBB, M.D.,
Physician to the British Cottage Hospital, Algiers.

IDIOPATHIC HAEMORRHAGE IN THE NEWBORN.

DR. G. H. ROBERTS's interesting memorandum on idiopathic haemorrhage in the *British Medical Journal* of January 12th (p. 68) tempts me to report a similar case of mine, which occurred a few weeks ago.

On December 13th, 1928, a primipara gave birth to an apparently healthy male child. Thirty hours later the child had a severe attack of melaena neonatorum and haematemesis, leaving it very exsanguinated and collapsed. Treatment with horse serum, small doses of adrenaline hydrochloride, and four-hourly subcutaneous and rectal salines, followed later with a mixture containing gelatin and glucose, resulted in recovery.

Four weeks later, the intervening period being uneventful, and the child breast-fed, I was again called in on account of a "swelling of baby's arm." I found the whole of the right arm, from fingers to shoulder, very swollen and suggestive of a cellulitis; there was also a similar swelling of the scrotum. Close inspection revealed no signs of focal infection; the umbilicus was normal and the temperature was 103° F. Breast-feeding was immediately stopped and the child put on glucose and sterile water, together with calomel 1/6 grain four-hourly. Twelve hours later the child was admitted to the Victoria Hospital. During the next three days the oedema, which "pitted" on pressure, slowly spread down the back, commencing over the scapula and later involving the chest. The temperature ranged between 100° and 104° F. On the third day after admission the oedema of the arm and scrotum had abated to a certain extent, but had extended to the head, face, and neck when death supervened. Treatment given in hospital consisted of "glaxo feeds," which were readily taken up to a few hours before the end, castor oil, and hydrarg. cum creta. Local applications of heat in the form of fomentations were applied to the arm. No necropsy was performed.

The most feasible explanation seems to be some inborn error of metabolism, but it would be interesting to hear the opinions of others on the subject.—I am, etc.,

Blackpool. HERBERT GEARY, M.R.C.S., L.R.C.P.Lond.

Reports of Societies.

THE CONSERVATIVE TREATMENT OF ECLAMPSI

AT a meeting of the Edinburgh Obstetrical Society January 9th, with the president, Dr. HAIG FERGUSON, the chair, Drs. DOUGLAS MILLER, ELSIE CROWE, and H. DAVIDSON contributed jointly a survey of 159 cases eclampsia treated by conservative methods.

Dr. Miller began by referring to the discussion on t prognosis and treatment of eclampsia which formed t principal subject for consideration at the Congress Obstetrics and Gynaecology in Liverpool in 1922. At t meeting the advantages of conservative over more radic methods of treatment were so convincingly emphasized the relatively low mortality in the Dublin group of cas that the Dublin method of treatment, with minor modific tions, had been employed as a routine in the Edinburg Royal Maternity Hospital during the period 1923-27 i clusive. Dr. Miller's contribution presented a survey of 1 cases of eclampsia treated by this method, and comprise an analysis of such symptoms and signs as coma, t number of fits, the degree of oedema, the degree albuminuria, blood pressure, pulse-rate, and temperatur in their relation to prognosis. The findings obtained con firmed in large part what was already believed in regard t the prognostic significance of these phenomena. An impor tant exception, however, was noted in regard to bloo pressure readings; in the series of cases studied th mortality ratio had proved to be in inverse proportion t the height of the blood pressure. When the systolic bloo pressure at the time of admission to hospital was under 150 mm. Hg a mortality of 27 per cent. was recorded; in a second group with blood pressures ranging from 150 mm. to 180 mm. the mortality ratio was 14 per cent; while in cases in which a blood pressure of over 180 mm. was noted the mortality rate was 13 per cent. No satisfactory explanation could be offered for figures so much at variance with what was generally believed in regard to the serious prognostic significance of high blood pressure in eclampsia. It was found that while the absence of oedema had been associated with a mortality of 24 per cent. the presence of this in marked degree had carried with it a death rate of over 30 per cent., a moderate degree of oedema being much less serious than either extreme. Further investigation showed that in each of the four fatal cases in which oedem had been absent death had resulted directly from intens toxaemia, whereas in the twelve fatal cases in which oedema had been extreme, pulmonary complications had contributed largely to the fatal issue in five cases, death in four of these being due directly to pulmonary oedema. It would appear, therefore, that while the absence of oedem was a sign of great danger, possibly because it implie concentration of toxins in vital tissues, extreme oedem carried with it a special risk of pulmonary involvement. The foetal and neo-natal deaths numbered 65, giving a mortality percentage of 39.1. The exclusion of 28 cas in which the child was delivered before the thirty-sixth week of pregnancy, and of 14 cases in which the child was believed to be dead at the time of the patient's admissio to hospital, gave a reduced foetal and neo-natal death rate of 18.5 per cent. There were 28 maternal deaths in th total series, a mortality ratio of 17.6 per cent. This figur compared with a mortality of 25 per cent. during the te year period 1912-21. The causes of death, confirmed i 22 cases by autopsy, were as follows: toxaemia 13 cas pulmonary complications 7 cases, cerebral haemorrha 6 cases, septicaemia and acute heart failure one case eac In conclusion, the speaker said that while in general th intensity of toxaemia could be reliably gauged by the ext and severity of the signs and symptoms specially consid it was necessary to bear in mind the notoriously uncer course which any case of eclampsia might follow, s even when the omens were favourable response to treat might suddenly and apparently without reason fail hopefulness be replaced by grave anxiety. In part it had been found in this series that the occurre cerebral haemorrhage had appeared to bear little r to the severity of the disease. In only one of the six ca

in which death was due to this complication had the toxaemia been so severe as of itself to make the prognosis anxious, nor in any of them had the systolic blood pressure exceeded 160 mm. In a haemorrhagic toxaemia of this nature the occurrence of haemorrhage in the brain, or, on the other hand, in some less vital tissue such as the liver, would appear to be largely a matter of chance, and an accident, accordingly, over which the attendant had little or no control.

Dr. ELSIE CROWE then gave a short summary of the chemical findings in 86 cases of eclampsia. As a result of these investigations she was led to the following conclusions. Almost all cases of eclampsia sustain renal damage, as shown by (1) a diminished power of excretion and of concentration of urea (MacLean's urea concentration test), and (2) a high blood urea content. The concentrating power of the kidney varies at the different stages of the illness, and may greatly improve as the patient's general condition responds to treatment. The normal blood urea in the second half of pregnancy is about 16 mg. per cent., while that of the average eclamptic patient is twice as high (32 mg. per cent.). She considered that the higher the blood urea figure rose the worse was the prognosis in most cases. Tests of hepatic function were of doubtful value; the large majority of cases showed definitely impaired excretory power when tested by Rosenthal's method (intravenous injection of a known quantity of phenol tetrachlorphthalein, and the estimation of the amount of dye removed from the blood stream by the liver in a given amount of time). Almost 50 per cent. of cases of eclampsia had positive van den Bergh and Fouchet reactions. These results had apparently little bearing on the clinical aspects of eclampsia, and were of no great prognostic value.

Dr. H. S. DAVIDSON concluded the joint contribution by referring to the high mortality in cases with low blood pressure; he thought this might be due to a profound affection of the myocardium by the toxaemia, thus lowering the blood pressure. The small number of deaths from heart failure associated with shock and collapse bore out the importance of refraining from interference in the ordinary case of eclampsia. He commented on the number of deaths from pulmonary oedema, and wondered whether oedema was directly traceable to the use of ether as an anaesthetic, or was merely part of the general oedema. It became a question whether, when an anaesthetic was required, chloroform should be given, as suggested by Stroganoff, or whether one should adopt some other form of narcosis, such as gas and oxygen. The Stroganoff treatment was very difficult to conduct in hospital; he could find no good purpose served by venesection which could not be as efficiently served by veratone. Dr. Davidson referred to the treatment of eclampsia by intravenous injection of magnesium sulphate, which he had been trying for the last six months with good results, although up to date only eight cases had been treated. Magnesium sulphate acted as a sedative and anticonvulsive agent, and produced a marked elimination by causing a large increase in the urinary output: this was followed by a marked diminution of oedema, which was probably general and affected the brain as well as other tissues. Dr. Davidson finally considered the treatment of the fulminating type of eclampsia, and mentioned the bad results obtained by any conservative method of treatment in such cases. He thought that by dealing with these cases by Caesarean section the prognosis might be improved.

DIFFERENTIAL DIAGNOSIS OF SPLENOMEGALY.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on January 11th, with the president, Dr. ROWLETTE, in the chair, Dr. J. LAIT read a communication on a case of splenomegaly, and showed the patient.

Dr. Lait said that the chief features of the illness were enlargement of the spleen with increasing anaemia; a low red cell count and a low haemoglobin percentage, with a colour index of about 1; the presence of "latent icterus" with a blood bilirubin of from 2.5 to 4.0 units; and a white cell count, when the patient first came under Dr. Lait's care, of about 15,000 per c.mm. The comparatively high white cell count and the marked splenic tumour were by themselves sufficient to rule out the diagnosis of pernicious anaemia, but earlier in the year the diagnosis of Banti's disease had been suggested. Study of the blood picture made it possible to refute this diagnosis, the blood film showing constantly almost every type of red cell and white cell precursor; moreover, the progress of the disease and its clinical features were unlike those of Banti's disease at any stage. Dr. Lait had no doubt that the case was a myelogenous leukaemia of the type described as a leuk-anaemia. Some authorities had discredited the existence of any such condition as a true intermediate form, but Dr. Lait brought forward cogent arguments in support of the aptness of the term. Dr. Lait's case notes of this patient afforded an interesting study in careful blood histology, as well as demonstrating the influence for good or evil of x-ray treatment on this rare disease. He concluded his communication with a short note on reticulocytes, in which he described the most recent theories of red cell formation, mentioning the place assigned to the reticulocyte in such schemes; the technique of staining was explained, and Dr. Lait insisted that *intra vitam* staining should become a recognized procedure in clinical work, on account of the prognostic importance of the reticulocyte in the liver treatment of pernicious anaemia.

The PRESIDENT, in discussing the paper, emphasized the importance of such careful study of diseases of the blood-forming organs in view of recent advances in therapeutics. Dr. L. ABRAHAMSON mentioned a case of myelogenous leukaemia which bore a close resemblance in its white cell count to that of Dr. Lait's patient.

TRAUMATIC RUPTURE OF THE URETHRA.

AT a meeting of the Section of Urology of the Royal Society of Medicine on January 24th, with Mr. SWIFT JOLY in the chair, a paper was read by Sir WILLIAM DE COURCY WHEELER of Dublin on traumatic rupture of the urethra.

Sir William Wheeler said that this was a rare accident, and so few cases had come under the care of any one surgeon that no settled form of treatment seemed to have evolved. Rupture was far more common in the bulbous portion of the urethra than in any other part. In France the accident was considered to be most frequent in young men, but he did not think that was the case everywhere; in the six cases on which his paper was based the average age was 42. Sometimes in this injury extravasation occurred in the anal region, the ischio-rectal fossae, and the thighs. When the rupture was situated well in front of the triangular ligament there was nearly always a perineal haematoma, and the patient was unable to gratify an intense desire to pass water. There was severe local pain. For the first several hours, fortunately, reflex spasm of the compressor urethrae prevented extravasation of urine, thus reducing the mortality. When the urethra had been only partially severed the bleeding was likely to be more profuse and continuous than when the rupture was complete. Severe traumatic stricture might follow injury without rupture. When associated with fractured pelvis the urethral rupture was more likely to be above the triangular ligament, in the region of the apex of the prostate. A ruptured bladder, being empty, could not be palpated. Usually the extent of the injury found to be present at operation was greater than the signs and symptoms immediately after the accident had led the surgeon to suppose; this fact strengthened the call for prompt operation. When a black patch appeared on the penis it probably meant that the whole corpus spongiosum was infiltrated with urine. Extravasation in recent traumatic cases had a better prognosis than in old cases; as a rule patients in the first instance were in good health when the accident happened. If operation was delayed, then (assuming the patient to be still alive) the parts became riddled with sinuses and urinary fistulae. The speaker urged the desirability of agreeing upon a uniform early treatment in these cases. An operation should not be approached hurriedly, and in this class of case very special precautions should be taken to ensure asepsis. He described in detail his own procedure. The literature showed general agreement as to the need of immediate suprapubic cystotomy in fresh cases of the accident, followed by retrograde catheterization.

Mr. RALPH THOMPSON commented on the very small proportion of urethral stricture cases which were traumatic, the average at two large hospitals being about 3 per cent. of the total urethral strictures. He urged the importance of operating to deal with the urethra as soon after the accident as possible.

Mr. FRANK KIDD mentioned the analysis he made, in 1921, of 57 cases of this accident treated at the London Hospital. That all except one of these patients remained alive indicated that the accident was not a real menace to life. From a careful study of cases he had arrived at the conclusion that the real origin of the stricture was pulping of the tissues. He was a strong advocate of a prompt suprapubic incision, under anaesthesia, followed by retrograde catheterization.

Mr. FOWLER WARD said that these ruptures in children who were brought quickly under care were not usually severe; the serious cases were in heavy men who were not seen for some days after the accident and who had not passed any urine since the accident. He much preferred silver to rubber catheters. Mr. WINSBURY WHITE reported a case of fractured pelvis, with partial rupture of the urethra; the result of treatment had been very satisfactory. Mr. CYRIL NITCH agreed with the opener's contentions, and described cases he had seen. Others who spoke in support of the opening thesis, and quoted cases, were Mr. HUGH LETT and Mr. G. E. NELIGAN; Sir WILLIAM WHEELER briefly replied.

POST-OPERATIVE ACIDOSIS.

AT a meeting of the Anaesthetic Section of the Royal Society of Medicine, on February 1st, Dr. R. D. LAWRENCE opened a discussion on post-operative acidosis.

Dr. Lawrence said he had purposely used the term "post-operative" so that any blame for the occurrence of the condition due to surgical manipulation could be included in the discussion. As he was neither a surgeon nor an anaesthetist he could claim to be impartial in the marshalling of his facts and deductions therefrom. The term "acidosis" was a loosely used one, and covered more than one condition. As applied to post-operative conditions it covered the presence of ketones and acetone bodies in the urine. These could be present without marked diminution of the alkaline reserve. The human body was always alkaline, but all its activities led to the production of carbonic acid equivalent to 300–400 c.cm. of concentrated hydrochloric acid. The alkalis were, however, always in excess. The mechanism of neutralization was interesting. If acid was added to water there was a marked change in the amount of free hydrogen ions. These ions determined the reaction of a fluid. If, however, the acid was added to blood there was no increase of the hydrogen-ion content of the blood, owing to the presence of what were known as "buffer substances." The chief of these was sodium bicarbonate, which formed the alkaline reserve in the blood. This salt was acted on by hydrochloric acid to form common salt, carbon dioxide, and water. The alkaline reserve in the blood varied from 55 to 75 volumes per cent. Ketosis could be present without definitely changing the ratio of the alkaline reserve. Chloroform, ether, and nitrous oxide all definitely reduced the alkaline reserve. The fall was rarely more than 10 volumes per cent. This began very soon after inhalation, and the ratio slowly returned to the normal after the second day. Ketonuria was much less frequent the day after operation, whereas acidosis was almost constantly present. The amount of ketones formed was so slight that it in no way represented the acidosis. Chloroform most frequently produced ketonuria, but spinal and local anaesthetics also produced the condition. Novocain decreased the alkaline reserve by five volumes per cent. in about half the cases investigated, and this occurred mostly in abdominal operations under novocain. Shock and fractures produced acidosis, and the condition was increased in nervous and anxious patients. It was difficult to explain the mechanism of the production of acidosis; the factors were complex and probably multiple. Sleep produced acidosis, and this was due to the insensitiveness of the respiratory centre at night, and its failure to respond to external changes. Under anaesthetics the respiratory centre was more depressed than in sleep. Anoxaemia produced acidosis. The glycogen store of the liver had been definitely depleted by anaesthesia. In normal individuals acidosis was of no importance; it could not be prevented, but it could be minimized. In patients with acidosis and no ketosis—for example, chronic nephritics and those suffering from wasting diseases—operations should be carried out as far as possible under spinal anaesthesia, and large doses of sodium bicarbonate, up to eight drachms a day, should be given for a few days before operation. In patients with ketonuria but no acidosis the position was more serious, since operation would increase the ketosis, especially if there was sepsis, and might lead to vomiting and liver damage. Chloroform was dangerous, as it might cause fatty degeneration. Ketonuria was a danger signal which we could not afford to ignore. The operation should if possible be postponed, and abundance of carbohydrate given by the mouth or intravenously. The ketonuria should then cease in from twenty-four to forty-eight hours. Insulin need not be given unless the ketonuria was very severe. In cases which did not brook delay nitrous oxide and oxygen, with or without ether, might be given, but chloroform never. In the case of diabetics, carbohydrates and insulin should be given, 20 units of insulin with 20 grams of sugar four-hourly. When possible a spinal anaesthetic should be given, but nitrous oxide, oxygen, and ether did not usually cause ill effects.

Dr. P. J. CAMMIDGE, while agreeing in the main with what Dr. Lawrence had said, thought that he had not sufficiently stressed the importance of the body cells. Difficulties ensuing from acidosis were due, not to the acidosis, but to changes in the cells themselves. Clinical changes were produced by alterations in the cells of the body. Variations in the water retention of the tissues brought about acidosis. Thus we found (1) acidosis from anhydraemia; (2) acidosis from over-production of normal acid products—for example, nephritis; (3) acidosis resulting from the removal of the alkaline bases of the cells; and (4) acidosis due to changes in the osmotic pressure between the cells and the plasma. A patient might have alkalosis after operation—for example, intestinal obstruction with vomiting. The chemical test for this condition was the finding of traces of acetone in the urine but an absence of chlorides. In these cases sodium chloride should be given with glucose. A special type of case was met with in children suffering from cyclic vomiting with headache. In this type the condition was inherited and the liver was below standard. Should operation be necessary in such a case it was best to substitute oatmeal for glucose in the preparation of the child for operation.

Professor E. C. DODDS said that in his experience acidosis was extremely rare, the chief causes being diabetes and starvation.

Dr. F. E. SHIPWAY had rarely seen acidosis in serious form. In these cases chloroform was to be avoided unless the patient had received careful preparation.

Mr. ZACHARY COPE cited cases in children in which, after operation under chloroform for appendicitis, vomiting, icterus, pallor, sweet-smelling breath, acetone in urine, delirium, screaming, and eventually death with central nervous irritation had ensued. He now insisted on ether being given in all such cases, and there had since been no fatalities due to acidosis.

VERTIGO.

AT a meeting of the Section of Otology of the Royal Society of Medicine on February 1st, with Mr. SOMERVILLE HASTINGS in the chair, a discussion took place on the nature of vertigo.

Mr. SYDNEY SCOTT, in opening, said that a hundred years ago the subject of vertigo resembled a tropical jungle, and even now there still remained large areas to be cleared. Hughlings Jackson was responsible for the definition of vertigo as a state of consciousness, attributable to incoordination of afferent impulses connected with the vestibular system. Destructive lesions of the labyrinth or of vestibular tracks were either partial or complete. It was in the early stage, where destruction was partial, that the patient suffered from vertigo; when the destruction was complete he suffered from deafness. If both ears were stimulated at the same time and in the same way there

was no vertigo, but if one side was stimulated, say, by irrigation with water at a different temperature from the other, vertigo occurred immediately. The sensitiveness of the labyrinth differed in different individuals, and was a very important factor. The clinical manifestations of vertigo were so widespread that sometimes the general practitioner was prevented from recognizing the possible cause. He had seen patients with attacks associated with vomiting who had had a gastro-jejunostomy done, or an appendix removed, when the real cause of the attacks was vertigo. Some patients complained of scalp pain; in others visual disturbances were an outstanding feature. A rare difficulty was diplopia during the attack. Staggering gait, vasomotor and cardio-vascular symptoms, pallor, flushing, sweating, dyspnœa, fainting, were all associated with vertigo, and he had come across attacks followed by violent diarrhœa. With regard to objective examination, he had found that a number of patients who had vertigo were undoubtedly the victims of some nasal trouble. Vertigo was associated with acute, non-perforative otitis media, with chronic otitis media, with labyrinthine fistula, with otosclerosis, and post-suppurative adhesions, with rhinitis, ethmoiditis, sinusitis, nasal polypi, post-nasal catarrh, and dental infections. Some years ago he had a patient with vertigo with no obvious cause, but it was eventually found that he had a strong Wassermann reaction. One had to bear in mind the possibility of syphilis in many of these cases. The principles of treatment were, first to seek the cause, which, if peripheral, might be removed by operations on the ear, nose, throat, or even by extracting dead teeth; if central, by intracranial surgery, decompression, or by neuropathic medical treatment.

Dr. LOWNDES YATES followed with an epidiascopic demonstration of some graphic records of instability, results of the past-pointing test, illustrative of certain cases which had been referred to by Mr. Scott.

Mr. A. R. TWEEDIE made a reference to the work of Andreas Högyes, and showed some pages of his book which indicated at what an early stage he had anticipated modern otology, although for a long time his work, because it was written in Magyar, remained unappreciated. Mr. Tweedie passed in review the rotation, caloric, and galvanic tests. He criticized the rotation test in certain respects, while affirming his belief that it should be continued in practice. He found the caloric and galvanic tests more valuable, though they, too, presented problems as yet unanswered; for example, neither of them was a definite test for the hysterical case. All cases of vertigo had an otitic factor, but the cases might be divided into two groups, in one of which the otitic factor was predominant (this group including inflammatory lesions and new growths), while in the other the factor was incidental. He brought forward seven cases belonging to the second group, in all of which there was asymmetry of auditory function and of function in the peripheral vestibular organs, and gave the results on these cases of the three tests named.

Mr. E. A. PETERS showed and described a case of a man, aged 74, who, in 1914, suffered from severe giddiness, and was often unable to cross a room. As the symptoms did not yield to treatment the left external semicircular canal was opened and the dura mater in Trautmann's triangle exposed. One end of a fine silkworm-gut suture was passed into the canal and the other between the dura mater and cranium. Relief of giddiness followed the operation. There was still (fifteen years afterwards) no giddiness, and the man could climb about on a scaffold. The drainage had been very effective, and the hearing was relatively better.

Mr. ERIC WATSON-WILLIAMS said that in true vertigo—that is, a condition in which the patient had a sense of rotation—there was something wrong with the ear or its intracranial connexions; if the patient merely had sensations of giddiness these might be due to the ear, no doubt, but they might be due to other things—to anæmia, constipation perhaps, or even atmospheric conditions. Often people were sent with a story of giddiness and sickness, and the inference was drawn that they got giddy because they were sick; but if there was true vertigo these people were sick because they were giddy—that is to say, to start with the ear was wrong. In the nineties Gowers said that after thirty years he had been forced to doubt whether there was true vertigo of gastric origin. Until a year ago he had been able to say that he had cured the last three "cerebral tumours" sent to him by removing wax from the ear. He had one case with facial paralysis and intense vertigo from which he had removed about half an ounce of wax from an enormous cavity, and the man got perfectly well; the case was sent in as meningitis. The most intense and lasting vertigo he had ever seen was in a man who, during his attacks, was unable to lie on the floor; he rolled across the floor unless he could clutch hold of something. Vertiginous cases which had particularly interested him lately included one or two in which he had been misled, and which turned out subsequently to be encephalitis. Encephalitis, apparently, occurred sometimes as a simple vestibular disturbance. In most types of encephalitis the vestibular nucleus was specially susceptible, and one might get auditory disturbance at the same time. He wished he could be told of some really reliable method of discriminating between a lesion of the labyrinth and a lesion of the brain—some method which could be carried out at the bedside without any elaborate test. He could not say that the galvanic test had helped him in this respect.

Mr. G. J. JENKINS congratulated Mr. Scott on establishing, what he had been teaching for years, that middle-ear affections might cause vertigo. The ear might be very seriously diseased with the labyrinthine affection, and yet the vertigo might be due to middle-ear changes, and not so much to the labyrinthine condition itself. The speaker mentioned one or two cases in children where removal of tonsils and adenoids cured the condition of giddiness.

Dr. STACEY WILSON pointed out that vertigo was an important cause of neurasthenia, especially in a lesser degree. As a physician he had found it of considerable interest to distinguish severe degrees of vertigo by the test as to whether the patient felt level in bed or not. If the patient felt the bed untrue it was a severe case.

TREATMENT OF EXOPHTHALMIC GOITRE.

AT a meeting of the Manchester Medical Society on November 7th, 1928, with Dr. R. W. MARSDEN, the president, in the chair, Dr. C. S. D. DON read a paper on the treatment of exophthalmic goitre.

Dr. Don compared the three lines of treatment at present adopted in cases of exophthalmic goitre—namely, iodine therapy, x-ray therapy, and operative procedures. Progress was estimated by comparing the basal metabolic rate, the weight, and the pulse in each case, before and after treatment. It was found that iodine caused a temporary diminution of the basal metabolic rate and the pulse and a gain in weight. The fall in the basal metabolic rate and pulse lasted for about a month, in some cases longer, while the increase in weight in nearly all cases continued for about five months. Iodine by itself could not cure exophthalmic goitre; a second course had less effect than the first one. Dr. Don said that a number of patients who had had x-ray therapy for periods over a year were examined repeatedly at intervals of three months, the basal metabolic rate being determined on each occasion; out of a total of thirty cases improvement or cure had been found to occur in 54 per cent.; in 27 per cent. the basal metabolic rate and pulse rate had returned to within normal limits, and this was regarded as a cure. Operative procedures were then considered, and attention was drawn to the value of iodine in preparing patients for operation. Of twelve cases examined not less than eight months after the date of operation, it was found that a fall in the basal metabolic rate and pulse to normal, accompanied by an increase in weight, had occurred in nine. Eighteen cases were examined before iodine was given, after administration, and two weeks after operation. As judged by the basal metabolic rate and pulse rate, cure had occurred in 85 per cent. Dr. Don advocated x-ray therapy without iodine administration for six months; after this, if the basal metabolic rate and pulse had not diminished considerably the patient should be given iodine, followed by an operation. Cases with basal metabolism of over *plus* 35 per cent. should be treated by preliminary ligaturing, while those in which the basal metabolic rate was below *plus* 35 per cent. should have four-fifths of the goitre removed by thyroidectomy.

GONORRHOEA IN THE FEMALE.

AT a meeting of the London Jewish Hospital Medical Society, held on January 17th, Dr. S. WOLFF opened a discussion on the treatment of gonorrhoea in the female. The speaker remarked that too little attention was given to this subject, considering the many devastating complications gonorrhoea was prone to set up in women. There was no generally accepted line of treatment; each treatment centre had its own routine, a lack of unanimity surprising in a disease so ancient and widespread. The fault was not so much with those in charge of clinics as with the patients themselves. It was very difficult to get a patient to realize the seriousness of the disease and the necessity for prolonged treatment. Many patients underwent no treatment at all, regarding the disease as a "chill" and the discharge as normal. It would help matters considerably if gonorrhoea in the female were treated only by women doctors; a better understanding between the doctor and the patient would be arrived at. No organized campaign against gonorrhoea could be successful if the problem of prostitution was not faced. The prostitute was the main carrier, and the treatment of this type of patient would probably become more effective if it were left to women doctors. At present it was left entirely to the goodwill of the prostitute whether she persevered with treatment, or even underwent any at all. If society could not abolish the prostitute it had to cultivate its sense of self-preservation. In the case of married women much education was required to make them realize that vaginal discharges were not normal concomitants of married life. Too many women were chronic invalids from neglected gonorrhoea.

THE LENS CAPSULE AND ACCOMMODATION.

AT a meeting of the Optical Society on January 17th, Mr. E. F. FINCHAM read a paper on the function of the lens capsule in the accommodation of the eye.

Mr. Fincham said that although abundant evidence was now available in support of the general principle of Helmholtz's theory of accommodation, no definite explanation had been given of the formation of the "lenticonus" discovered by Tscherning, which led him to challenge that theory. In 1925 the speaker had suggested that the varying thickness of the capsule covering the anterior surface of the lens would account for the type of surface which Tscherning had depicted. Mr. Fincham described the determination of the form of the anterior surface of the lenses of freshly dead animals, by photographic records of the image reflected from the surface. The lenses of a number of different species were examined and records were made when the lens was held under tension by its normal suspensions and also when the suspensions were removed. The thickness of the capsule in each case was then measured microscopically. The results showed that in primates the anterior surface of the lens assumed a somewhat conical form with an area of increased curvature in the centre, when the suspensions were severed. The capsule of the primate lens had a zone of increased thickness surrounding a central thin area. Photographs of the profile view of a monkey's lens, which was removed from the eye and suspended in oil, revealed it in the typical accommodated form. A similar view of the lens without its capsule showed a close approach to the unaccommodated form. The anterior lens capsule of animals of an order lower than the primates was found to be approximately uniform in thickness. The "lenticonus" was not found in these cases, and the removal of the capsule did not cause an appreciable change in the form of the lens. From these findings the theory was formulated that accommodation consisted of a relaxation of tension upon the lens by the contraction of the ciliary muscle as stated by Helmholtz. This relaxation allowed the capsule to press upon the lens substance and mould it into the accommodated form. In the unaccommodated state the tension under which the lens was held by its supporting fibres did not permit this compression. The unaccommodated lens substance was therefore in its unrestricted or natural form and not under compression as supposed in the Helmholtz theory.

Reviews.

DISEASES OF CHILDREN.

Diseases of Children,[1] by Garrod, Batten, and Thursfield, has earned for itself a place as a standard textbook, and for this reason the second edition, under the capable editorship of Dr. HUGH THURSFIELD and Dr. DONALD PATERSON, is extremely welcome. Like the first edition, which appeared in 1913, the present book has numerous contributors, thirty-six in all, each one chosen because of his particular knowledge of the subject about which he writes. As all the contributors, with the exception of Dr. Leonard Parsons of Birmingham and Dr. J. C. Spence of Newcastle, are or have been attached to London schools, the book may be taken as representative of London opinion on the subject of paediatrics at the present day. Like its predecessor, also, it is essentially clinical, and this is indeed fortunate. During the past decade research in paediatrics has been exceedingly active, particularly along biochemical lines and in the field of nutritional diseases. A repetition of this work is not, however, needed in such a book as this, since there is already a surfeit of smaller books each claiming to be of value in presenting the newer aspects of the subject to the already overtaxed physician. At the same time much new and valuable work of a clinical nature has been accomplished, and thus the editors were faced with the need for extensive revision. This has been most successfully achieved, the newer work receiving adequate recognition, while nothing of value has been omitted, with the possible exception of prematurity, which might with advantage have been discussed. The new edition follows almost exactly the arrangement of the original volume, with the addition of a short chapter at the end on diseases of the eye. This seems rather sketchy and incomplete, and might well have been omitted. The chapters on organic diseases of the nervous system and diseases of the muscles, by the late Dr. F. E. Batten and revised by Dr. W. G. Wyllie, and the chapter on diseases of bones and joints, by Sir Humphry Rolleston and Mr. H. A. T. Fairbank, are deserving of special attention for their completeness and lucidity; if they stood alone these contributions would establish the value of the book as a work of reference. Diseases of the ductless glands are discussed by Dr. E. A. Cockayne in a short and well-written chapter, which should prove of great interest to medical students and general physicians alike. The chapter on diseases of the newborn, by Dr. Langmead, has for the most part appeared unaltered. This is unfortunate. Certain statements here will not find general acceptance, particularly the remarks about haemorrhage of the newborn. This condition is a definite clinical entity which should not be confused with sepsis. Furthermore, the treatment, which is specific and so satisfactory, is only mentioned casually. The debatable subject of the feeding of infants has been dealt with by Dr. Edmund Cautley and Dr. Donald Paterson, and a huge amount of useful information regarding the preparation and the virtues of the various foods is given. A specific method of feeding infants is outlined which should prove a ready guide for the practitioner. We note that, in the chapter on diseases of nutrition, lactic acid milk receives credit almost to the exclusion of other types of feed—a view which many will find difficult to endorse. On the other hand, the well-recognized and valuable properties of protein milk (*Finkelstein's Eiweissmilch*) are given only scanty recognition. The chapters dealing with diseases of the heart, lungs, alimentary system, metabolism, etc., represent for the most part the usual current opinions, and on the whole are well balanced. The size of the volume has not been increased. It is sufficiently well illustrated, but contains only a meagre bibliography, or, in some chapters, none at all. This detracts perhaps from the value of the discussion of the more controversial subjects.

The book in this new form will carry on the reputation achieved by the first edition. It should appeal to a wide circle of readers, and we can recommend it with confidence to both students and practitioners. It is, in short, a worthy product of the London schools.

[1] *Diseases of Children*. Second edition, edited by Hugh Thursfield, D.M.Oxon., F.R.C.P., and Donald Paterson, M.B.Ed., M.R.C.P. London: E. Arnold and Co. 1929. (6½ × 9¼, pp. xi + 1106; 201 figures. 42s. net.)

DIGESTION AND GASTRIC DISEASE.

It is not surprising that Professor HUGH MACLEAN's volume in his Monograph Series, entitled *Modern Views on Digestion and Gastric Disease*,[1] has rapidly passed into a second edition. In view of the very considerable discussion on gastric and duodenal ulcer during the past year, in which the author has taken a part, especially in his lecture on the efficiency of the intensive alkaline treatment of these ulcers (vide *British Medical Journal*, 1928, i, 619), this fresh edition is appropriate as tending to maintain a balance of opinion and as a counterblast to Sir Berkeley Moynihan's outspoken condemnation of ordinary medical treatment as "highly dangerous" in his Lloyd Roberts Lecture published on December 8th last. Professor MacLean has in no way modified his vigorous opposition to the belief that ulcer is an important etiological factor in gastric carcinoma, which he describes as "really an acute disease" usually arising *de novo*, and not in more than 5 per cent. of patients with previous ulcer or long-continued dyspepsia. Further, the microscopical evidence of malignant change in chronic gastric ulcers—islands and ingrowths of epithelium in fibrous tissue—is, with the support of Sir Bernard Spilsbury and Professor Dible, gravely impugned. The importance of a decision on the reputed etiological sequence of gastric ulcer and carcinoma is obvious; for if it is true, every gastric ulcer should logically be excised.

In the chapter on the physiology of digestion Professor MacLean discusses the occurrence of regurgitation of the duodenal contents into the stomach, described by Drs. C. Bolton and G. W. Goodhart in 1922, and the reduction of hydrochloric acid and the associated increase in neutral chlorides during digestion. The normal occurrence of duodenal regurgitation was accepted in the first edition of this work, but now he concludes that, though duodenal regurgitation may occur, it is an accident and is not in any way part of physiological digestion. This change of opinion is based on examination of the gastric contents and on experimental observations on an isolated Pavlov pouch in the stomachs of dogs; and as a result the deduction is drawn that the stomach has the power of secreting both acid and sodium chloride, but when the secretion of one is copious, that of the other is low, and that the stomach possesses an automatic mechanism for regulating the hydrochloric acid concentration, so that when it reaches about 0.2 per cent. the secretion of acid is reflexly inhibited while that of sodium chloride continues.

The clinical, chemical, and radiological aspects of gastric diseases, the last by Dr. Geoffrey Fildes, are clearly dealt with, and there is much sound practical advice in the sections on diagnosis and treatment. Thus in the differential diagnosis between the dyspeptic pain of gastric ulcer and gall-stones stress is laid on the sudden relief as incompatible with ulcer; and further, whenever a patient over 40 years of age complains for the first time of dyspepsia without apparent cause, cancer should be suspected.

SURGICAL PATHOLOGY.

THE *Précis de Pathologie Chirurgicale*,[2] by a number of French surgeons, now in its fifth edition, is designed for the use of students preparing for examination and for practitioners desirous of keeping their knowledge abreast of the times. As a summary of surgical pathology it must be considered to be tolerably complete, since its six volumes include nearly 5,500 pages. Unlike many works on this subject, it includes the pathology of the female genital organs; on the other hand, while tumours of the orbit are considered at length, the surgical affections of the globe of the eye find no place in the book. The subjects embraced under the term "pathology" are made to include etiology, symptomatology, pathological anatomy, diagnosis, prognosis, and treatment; the book is therefore practically a textbook of surgery, except that the technical details of operations are altogether omitted.

The general arrangement follows the usual plan adopted in such works; the first part deals with lesions generally, the second with lesions of the tissues, and the third with lesions of the various regions of the body. As with many French textbooks, classification is strongly in evidence, and the descriptions, instead of being continuous, are for the most part divided up into sections under headings and subheadings, a feature which certainly facilitates reference and renders a survey of the whole subject more easy. With regard to the classification of tumours, the basis adopted is that almost universally recognized—namely, tissue structure—but the nomenclature differs somewhat from our own in that the term "epithelioma" takes the place of "carcinoma." The authors state that the term "carcinoma" has reference merely to a particular variety of epithelioma in which the connective tissue is arranged in the form of alveoli, the stroma sometimes being abundant, as in scirrhous carcinoma. Such terms, they consider, have now merely a historical interest and should be discarded. It is unfortunate that some common system of classification cannot be adopted in all countries, but of this there seems little prospect at present, and the nomenclature tends rather to become more confused. For example, we now find the term "adamantinoma," which is defined as arising from vestiges of dental structures in the jaw, applied by some authors to growths arising at the base of the brain; "meningioma," to growths of any kind arising in the meninges; "folliculoma," to a peculiar epithelial tumour arising in the follicles of the skin; and "Schwannoma," to the plexiform neuromas occurring in von Recklinghausen's disease, and supposed by some to take origin in the sheath of Schwann. The authors' system of classification breaks down somewhat in placing the multilocular cyst of the jaw and the multilocular and papilliferous cysts of the ovary under the *epitheliomas*; they admit that this is illogical. It may be noted that lymphadenoma is placed among the neoplasms, a position which would probably not be accepted by the majority of pathologists in this country; in structure it seems more allied to the granulomata.

In a work embracing the whole domain of surgical pathology it is interesting to note to what extent the use of radium is recommended in the treatment of malignant tumours. Irradiation, it is stated, has shown some remarkable results in lymphosarcoma of the skin and cervical glands, and in the latter case appears to be preferable to operation. In certain inoperable and recurrent sarcomas of the maxillae, x rays and radium have induced retrocession of the tumours, and in some very malignant forms would seem to be the treatment of choice. But with regard to sarcomata of bone generally radium is said to be of little use, and x rays may increase the tendency to metastasis in the round-celled form; in some hands the spindle-celled form has been found more amenable. Amelioration in the course of sarcomas of the nasopharynx may follow the use of x rays, and irradiation is useful as supplementing operative treatment of malignant tumours of the nasal fossae. In sarcoma of the uterus x rays are stated to give results comparable to those following operation. A large proportion of cases of rodent carcinoma are curable by irradiation, and good results have been obtained in cancer of the lip when irradiation is followed by complete excision of the glands. In cancer of the tongue radium therapy appears to be recognized as a satisfactory alternative to operative treatment, although it is too early yet to judge of the ultimate results. The modus operandi is to perform a bilateral excision of the glands, destroy the tumour by irradiation, and finally apply x rays to the gland zone operated on. In cancer of the larynx, oesophagus, and bladder, irradiation is only mentioned here as supplementing operation or as a palliative. In the case of the bladder, apparent cures are reported from the use of radium, but extremely painful burns may result from the treatment. Similarly with regard to cancer of the vagina, much relief is obtainable, but there is a great tendency to the formation of fistulae and other infirmities. Radium has given good results in cancer of the penis, preferably followed by the application of x rays to the glands; and in cancer of the prostate rapid and marked amelioration is obtainable, equivalent to cure in old people.

[1] Modern Views on *Digestion and Gastric Disease*. By Hugh MacLean, M.D., D.Sc., F.R.C.P. Second edition. Modern Medical Monographs. London: Constable and Co., Ltd. 1928. (Demy 8vo, pp. x + 182; 23 figures. 12s. net.)

[2] *Précis de Pathologie Chirurgicale*. Par P. Lecène, L. Tixier, et M. Patel. Cinquième édition, entièrement refondue. Collection de Précis Médicaux. Tomes i, ii, iii, iv, v, vi. Paris: Masson et Cie. 1928. (Post 8vo; illustrated. Paper cover, 45 fr.; bound, 55 fr. each volume.)

In the hands of expert technicians the employment of irradiation in cases of cancer of the cervix uteri appears to have been more or less systematized; in early operable cases radium and operation appear to be placed on an equal footing; in cases of doubtful operability and in inoperable cases radium in association with *x* rays is indicated. It will thus be seen that while irradiation is recognized by the authors of this work as being a powerful therapeutic agent, there is no very strong recommendation, in the majority of cases, to employ it as the method of choice. In France, as in this country, the indications for its employment will no doubt become clearer when its technique is better understood.

The Précis de Pathologie is written with the usual clearness and conciseness that one expects to find in French literary works. The volumes are handy in size, and contain a sufficient number of good illustrations without being overburdened with figures. As a manual for students and practitioners its popularity is well deserved.

HISTORICAL ASPECTS OF TUBERCULOSIS.

IT is only occasionally that any work appears to which the epithet "monumental" may justly be applied, but *La Tubercolosi*[1] seems fully to merit that description. This work has been prepared and published by the sixth conference of the International Anti-Tuberculosis Union, under the auspices, and with the co-operation, of the Public Health Department of the Italian Ministry of the Interior. It has been planned on generous lines, and consists of four large, well-printed volumes, with considerably over 3,000 pages, so that its scale permits the comprehensive treatment of various aspects of the problem of tuberculosis. Professor Ettore Marchiafava contributes a preface, and the various sections making up the nine parts of this work have been contributed by other Italian authorities, with Dr. Alessandro Messea, *director-general of public health*, as editor. As an example of the method followed the composition of the first part may be indicated; this section of the work, by Professor Guglielmo Bilancioni of Pisa, deals with the historical development of our knowledge of tuberculosis, and comprises a general survey, occupying some 140 pages, followed by a chronological exposition occupying 350 pages. It is interesting to observe how, from the few obscure references—drawn mainly from the literature of archaeology and palaeopathology—relating to the disease in the period 2000–1000 B.C., the stream gathers volume with the development of knowledge in general, the rise of scientific medicine, and the multiplication of written records down to 1850, when a vast literature had been accumulated. Professor Bilancioni has drawn upon a wide field for his citations; between 1300 and 1400 A.D. there are, for example, quotations from Dante and Boccaccio, but in later years the references are, of course, almost exclusively to the writings of medical men. The same author contributes a similar historical review of laryngeal tuberculosis, extending his chronological exposition of this topic down to the beginning of 1928. Other parts deal with various aspects of tuberculosis—bacteriological, etiological, immunological, the relation of the disease in animals to that in man, mortality statistics, hospitalization, therapeutics, and legislation. Each section includes a full index and, where applicable, a chronological survey. In the part devoted to legislation the multitudinous citations are also given in alphabetical order under the 160 states to which they relate. The history of the various national and international movements, and of the conferences and publications associated with them, is also dealt with in detail.

It will be clear from what has been said that this work should prove of considerable value and interest to research workers and others concerned with the problem of tuberculosis, notably in its historical aspects. Its sponsors and contributors deserve every credit for the material support which has made its production possible, and for the patient and laborious work involved in its compilation. The four volumes received for review have been placed in the library of the British Medical Association.

A SURGICAL TEXTBOOK.

PROFESSOR W. WAYNE BABCOCK'S new *Text-Book of Surgery*[2] takes a distinguished place among the many general textbooks that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background. Professor Babcock likes to be dogmatic in stating what he believes to be the truth at the moment of writing. He will still be dogmatic when he has progressed to an opposite standpoint, and the result is clarity of exposition. Except for a few specialties such as ophthalmology, otorhinology, and gynaecology, the whole ground of surgery is covered, including operative technique, and the survey seems to be extremely thorough. The personal note is often sounded in spite of the pervading brevity, and the reader is introduced in many places to Babcock's peculiarities of technique or instruments. This leads occasionally to a slight loss of balance, as when five pages are devoted to "Babcock's operation" for inguinal hernia, whereas the whole subject of the treatment of femoral hernia is dismissed in a few lines. One of the best features of the book is the quality of the very numerous illustrations, which have been carried out "in accord with the best traditions of the Max Brödel School."

SIGNIFICANCE OF THE COLLOIDAL STATE IN HEALTH AND DISEASE.

DR. AUGUSTE LUMIÈRE, who is the author of several smaller works on the same subject, has now brought out a book of more than 500 pages, *La Vie, la Maladie et la Mort: Phénomènes colloïdaux*,[6] giving a lengthy account of his thesis that healthy life depends on the maintenance of a normal colloidal state, and that destruction of this colloidal state is the cause of disease and death. Starting with this hypothesis six years ago, the author has made a large number of experiments which convince him that the problem has now been shown to be scientifically confirmed. When the structure of the colloids in the body is broken down a precipitation or flocculation occurs. In an animal intravascular injection of a fine suspension of an insoluble mineral, such as barium sulphate, produces acute symptoms resembling those of anaphylactic shock, which are explained as due to irritation of the endovascular terminations of the sympathetic. Experiments are also reported to show that traumatic shock is due to precipitation in the blood stream of colloids as a result of admixture of those liberated from the injured tissues with those of the blood plasma. When pathogenic micro-organisms produce precipitation in the blood stream, manifestations such as anaphylaxis, asthma, epilepsy, and acute disease result. Chronic disease is also explained by precipitation from the colloids, the cells of the various organs, and not the blood stream, being the site of the deposit. The various chronic diseases are determined by the organ or organs in which the precipitation chiefly occurs. The author unfortunately allows himself to express rather strongly his soreness that his views have not received more notice and acceptance.

NOTES ON BOOKS.

THE appearance of a second edition of Dr. SANSUM'S *The Normal Diet*[7] testifies to its success. This type of book is more popular in the United States than in this country; it seeks to place before the general reader certain problems commonly dealt with by the physician. While some of the subject-matter can be easily followed without any special knowledge, it remains a matter of opinion whether the lay public (and especially that section of it which is already seeking medical advice) benefits by a discussion of questions that do not yet admit of final or authoritative answer on the part of the medical profession; such matters Dr. Sansum has discussed in the section dealing with acidosis and high blood pressure. On the other hand, a grasp of the more general principles of diet might well save many patients a good deal of avoidable worry and discomfort.

[2] *Text-Book of Surgery.* By W. Wayne Babcock, M.D., F.A.C.S. Philadelphia and London: W. B. Saunders Co. 1928. (6½ × 10, pp. 1041 figures, 9 plates. 45s. net.)

[6] *La Vie, la Maladie et la Mort: Phénomènes colloïdaux.* Par Auguste Lumière. Paris: Masson et Cie. 1928. (Demy 8vo, pp. xiii + 55 illustrations, of which 17 are coloured plates. 25 fr.)

[7] *The Normal Diet.* By W. D. Sansum, M.S., M.D., F.A.C.P. Second edition. London: H. Kimpton. (Post 8vo, pp. 136. 6s. 6d. net.)

Those who wish to obtain a short account of the procedure adopted by a practitioner who uses tuberculin in treatment and diagnosis will find it in Lieut.-Colonel F. E. GUNTER'S *Tuberculin in Practice*.[8] Recognizing the danger of the indiscriminate use of this agent the author advises the novice to begin with the application of tuberculin liniment rather than injections; to confine himself at first to early cases of the disease; and to take every opportunity of attending an institution, such as a dispensary, where tuberculin is given. For diagnosis he suggests the modified von Pirquet procedure, and does not mention the more modern intracutaneous injection of tuberculin. His summary of Koch's investigation at the beginning of the book is too brief to be intelligible. In a postscript there is a portion of a letter received by the author from Professor Calmette, in which it is stated that "the favourable action of tuberculin is entirely due to the presence of phosphatoids and lipoids."

Professor FEER'S well-known book on *The Diagnosis of Children's Diseases*[9] was first translated into English by Dr. C. A. SCHERER in 1925, and a second edition of this translation now appears. The original translation was made from Feer's third edition, and it is not clear which edition has been used for this revised version now issued. It is stated by Dr. Scherer that "the advance of knowledge . . . even in two years has necessitated numerous additions," but whether these additions have been made in Zürich or Minnesota is not revealed. Little need be said here about the contents of the book except to recall that diagnosis alone is dealt with, and that the illustrations are a remarkable feature of a well-produced volume. Disorders of the skin are taken up at considerable length, and this particular section is one of the best in the book.

LERICHE and POLICARD'S book on *The Normal and Pathological Physiology of Bone*,[10] which has already been noticed in our issue of October 9th, 1926 (p. 639), has now been translated from the French by Professors MOORE and KEY of the University of Washington. It contains a new theory of bone formation, the main features of which are as follows. The osteoblasts are not bone producers, but bone destroyers, their function in this respect being feeble, although indirectly important owing to their capability of becoming converted into osteoclasts. Bone is not a tissue *sui generis*, but merely one of the many forms into which embryonic tissue may become transformed under varying conditions—such as areolar tissue, fibrous and tendinous tissue, mucous tissue, hyaline tissue, and cartilage. What the precise conditions are which determine the production of one form rather than another is a matter for further research, but in the case of bone formation an abundance of calcium salts in solution in the fluids of the part appears to be one of the necessary conditions. All bone formation takes place in membrane, endochondral ossification being no exception, since bone is not formed until the cartilage has been replaced by connective tissue. In an area in which bone formation is taking place the first change is a reversion of the connective tissue to the form of fibrillated embryonic connective tissue; next there is a marked proliferation of the fibrillae; this is followed by an exudate in the form of a semi-solid oedema, in which calcareous deposition takes place, the cells of the original tissue becoming imprisoned as passive bone corpuscles. The osteoblasts are regarded as connective tissue cells which have become hypertrophied under the influence of their altered surroundings, the change being regarded as to some extent a defensive action.

Modern X-Ray Technic,[11] by Dr. E. C. JERMAN, is very American in its construction, as well as in the manner in which the subject is dealt with and discussed. Apparently the author has the teaching of a large number of x-ray technicians, and has written mainly for them, and also in the hope that the book may be of use to technicians generally. The second section, which is illustrated, shows page by page a photograph of the part under examination, with the radiographic result; and, in addition, there is a short account of the technique, and a table of exposures in varying circumstances. The book is well presented, and contains a great deal of useful information, set out in a somewhat dramatic manner.

A Text-Book of Biologic Assays,[12] by P. S. PITTENGER, is a second edition of a book that was published as long ago as 1914, but the subject has changed completely since that date, and the present volume is practically a new work. In a work of this character the points of outstanding importance are that the methods mentioned should be described with sufficient detail to enable the reader to perform the tests himself, and that the standard of accuracy should be high. Unfortunately the book does not always fulfil these requirements. Important practical points are omitted in the descriptions of some of the methods, and also some methods that have been proved to be unreliable are included. The book concludes with three pages of references, but there are only three references to work done outside America since 1914.

In a pamphlet entitled *Clinical Surgery*[13] Mr. J. W. DOWDEN of Edinburgh has provided a useful collection of hints for junior students from which may be acquired as much of the wisdom of an experienced and skilful surgeon as can be conveyed by way of precept. How to observe, how to examine patients, and how to record the results of observation and examination (including in this last term anamnesis) may be learned from these few clearly printed pages.

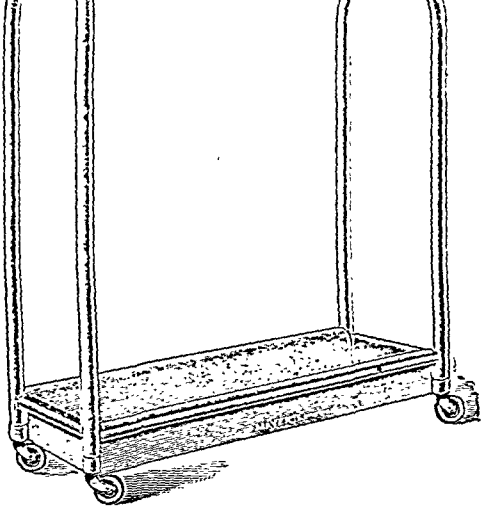
PREPARATIONS AND APPLIANCES.

ABDOMINAL SWAB STAND.

DR. W. R. MACKENZIE (Belfast) has designed a mobile stand fitted with hooks upon which abdominal swabs may be hung after use, a removable tray catching the drips. The apparatus makes it possible for the surgeon or sister in charge to see and count the swabs, and thus minimizes the danger of one



or more being overlooked. The illustration shows the stand fitted with fourteen hooks, a number found useful for abdominal work, but stands with any number of hooks can be supplied. The apparatus runs very easily on ball-bearing castors, and forms a most useful piece of furniture for the operation theatre. The apparatus is made for the Samaritan Hospital, Belfast, by Messrs. Mayer and Phelps (49, New Cavendish Street, W.1).

ANAESTHETIC ETHER.

We are informed by Messrs. Howards and Sons Ltd. that their standard ether for anaesthesia, which has previously been made from industrial methylated spirit, is now produced entirely from duty-free rectified spirit, and at no stage in its manufacture are deleterious denaturants, such as wood spirit and pyridine, added. The standard ether is supplied at the same price as that formerly charged for ether made from industrial methylated spirit.

AN EMERGENCY DRESSING.

We have received from Mr. H. H. ARNOLD (81, St. George's Road, S.W.1) a small antiseptic dressing, capable of being carried in the pocket, for emergencies. It consists of iodine in a semi-solid form, a small dressing of sterile lint or gauze, and adhesive strapping, and is designed to facilitate the rapid sterilization of wounds. The price of the dressing is stated as 2s.

RADIUM IN THE TREATMENT OF MALIGNANT DISEASE.

LECTURE BY PROFESSOR GASK AT THE ROYAL COLLEGE OF SURGEONS.

A HUNTERIAN LECTURE on the use of radium and its emanations in the treatment of various forms of malignant disease was delivered by Professor G. E. GASK at the Royal College of Surgeons of England on January 30th. The lecture was a survey of the results of this treatment as obtained by the Surgical Unit at St. Bartholomew's Hospital, and was followed by a demonstration in the library of the College of patients who had been treated by radium. Professor Gask explained that he was acting only as the mouthpiece of the Surgical Unit, and was describing work which had been carried out by a team. He was fully conscious of the great amount of excellent work done abroad and in this country; if he did not refer further to it, it was not from want of appreciation, but because he thought his audience would prefer to learn the results of the particular investigation of which he could speak with personal knowledge.

Clinical Results.

In 1921, with some radium loaned to the Surgical Unit by the Medical Research Council, a start was made on the treatment of sarcoma; four patients were treated, of whom only one remained alive. The treatment employed at first was to implant a tube containing a large dose of radium in the middle of the tumour, and leave it there for a short time. In 1922 five patients with sarcoma were treated, of whom again only one remained alive. The treatment of sarcoma was disappointing, and, moreover, no large number of cases was available; therefore an attempt was made on carcinoma of the breast, only cases of recurrence, too advanced for further operative treatment, being taken. These were treated in the same manner, with the buried tube, but again the results were almost uniformly bad. Of three such patients treated in 1922, two in 1923, and two in 1924, not one remained alive.

In 1924 the first case of primary carcinoma was taken. While radium was found to have a very considerable action on the tumour, these cases of advanced growth, where there was metastasis, went on to a fatal issue. It was also clear that radium was not distributed far enough or evenly enough. The technique was changed, therefore, a smaller dose being given for a longer time. The first patient with primary carcinoma, treated in 1924, remained alive and well to-day. In 1925 six such patients were treated, of whom two remained alive, and in 1926 of another six, four remained alive. Of the thirteen treated in 1927 ten remained alive, and all the thirty-nine treated in 1928 had survived so far. The technique, which had been gradually evolved, was to insert a large number of needles —up to thirty-five—placing them underneath the breast, between the breast and the pectoral fascia, so as to make a kind of barrage; the axillae were dealt with in a similar manner. In one such patient in whom the carcinoma of the breast was well marked, the growth disappeared four months after radium treatment. After mentioning other striking cases of the same kind, the lecturer remarked that it was quite clear that a stage had been reached at which the immediate results of radium treatment could be pronounced satisfactory. The tumours shrivelled, fungating ulcers vanished, and the glands cleared up. This had not happened once or twice, but time and time again.

The Nature of the Curative Process.

Professor Gask said it was interesting to speculate what happened when radium was applied to a tumour. Physicists had suggested that the result might be due to an enormous agitation of electrons which caused heating of the cells and killed them by coagulation of the protein, but now there appeared to be some scepticism as to the very existence of the electron. While it could not be stated what was going on in the cell, some interesting experiments had been conducted by Dr. Canti and others. The lecturer exhibited a box of mustard and cress in the middle of which radon seeds had been inserted. In this spot the plant did not grow, and surrounding this area was a fringe of stunted growth. He also showed on the screen a section from a well-marked carcinoma of the breast. This patient, after five months, still had a lump in the breast, and it was uncertain whether the tumour was still alive. A local excision was therefore made, and the carcinoma disappeared, only necrotic tissue being left.

Ultimate Results of Radium Treatment.

As regards the final results of treatment, Professor Gask said that time must elapse before it would be possible to make any definite pronouncement. But as a basis of comparison he had taken a chart from the "follow-up" department at St. Bartholomew's showing the survival rate among women who had had various kinds of operations on the breast for carcinoma. The results were, he thought, appalling. At the end of six months only 85 per cent. were alive; at the end of two years about 60 per cent., after three years 50 per cent., and at the end of six years, which was the full period covered, 20 per cent. Thinking that this might possibly be exceptional, he inquired from Mr. Miles as to the statistics for the Cancer Hospital, and from these it appeared that ten years after operation the survival rate was only 20 per cent.

Technique of Radium Therapy.

Professor Gask then proceeded to speak about the introduction of radon seeds, which had the advantage that they could be used in very small confined spaces. The seeds were placed at the periphery of the tumour in such a manner that the whole tumour was irradiated. The first case in which this method was applied was a fungating epithelioma of the tongue; it cleared up in a remarkable way, the like of which he had never seen, with the exception of the disappearance of some gummas under the influence of iodide treatment. He showed lantern views of several cases of epithelioma of the tongue, with a good result in almost every instance. The problem remained how to deal with the glands, and Professor Gask illustrated the way in which needles, each containing 1, 2, or 3 mg. of radium element, were placed over the area.

With regard to tumours of the brain, it was thought that it might be possible to expose the brain tumour and leave radium in position. A case of commencing acromegaly in a woman presented itself; the pituitary tumour was exposed, and one radon seed inserted. The patient lost her symptoms, including headache; her fields of vision became normal, and she was very grateful. It was arguable, of course, that the manifest benefit was due to decompression, and not to radium treatment; on this he ventured no opinion. He related other dramatic cases in which radon seeds had been inserted in brain tumours, resulting in enormous improvement. One woman with a glioma had had ten radon seeds inserted with remarkable benefit, though here again the good result might be due to decompression. With regard to other internal tumours, attempts had been made to treat these in the same manner, so far without much progress.

In conclusion, Professor Gask said that it might fairly be claimed that Madame Curie and the physicists had placed in the hands of the medical profession a new and very potent weapon, of the extent and power of which they were not yet fully aware; that it was useful he was convinced. He confidently hoped that many of these cases, the like of which had previously been treated by operation, could now be cured by this method. Yet a note of warning must be sounded for those who were about to take up the use of radium, which, like all potent agencies in medicine, might be active for evil as well as for good. Surely Shakespeare might be held to have foreseen this when he bade us beware lest we heal the inveterate cancer of one wound by making many.

After the lecture a demonstration was given by members of the Surgical Unit of a remarkable series of forty-nine patients who were gathered in the library of the College. These patients had been suffering from various forms of malignant disease—of breast, tongue, floor of mouth, larynx, pharynx, and brain—and all had been treated either with radium or radium emanations. In all of them the original tumour from which they had suffered had disappeared, and they remained apparently well. Patients were shown in all stages of duration of treatment, from four years to three weeks.

British Medical Journal.

SATURDAY, FEBRUARY 9TH, 1929.

THE SURGERY OF PROSTATIC ENLARGEMENT.

IN recent numbers of the *British Medical Journal* have appeared various communications on the subject of prostatic enlargement, notably the address by Mr. Cyril Nitch published on January 26th (p. 139), and that by Professor Grey Turner in our present issue at page 233. A careful study of these papers provides a standpoint from which the present position of the surgery of prostatic enlargement may be surveyed. All writers agree that much progress has been made in the treatment of this condition during the last decade. The operative mortality, although still high, is on the decline. Great improvements have been achieved in operative technique, and still more in pre-operative treatment and post-operative care. The introduction of the two-stage operation of prostatectomy in itself has been instrumental in saving many lives. So also has been the spread of the knowledge of tests of renal efficiency. But when we turn to the pathology of enlargement we must confess that our knowledge is little more than that of the old Venetian physician of the sixteenth century, Nicola Massa, in whose writings the first reference to prostatic enlargement is found. The causes and nature of the disease are still unknown. In the last ten years no new facts have been gleaned which will enable us to decide between the rival theories of inflammation, new growth, and degeneration. Each explanation of enlargement has its partisans, but, as Mr. Nitch has stated in his paper, the theories most worthy of consideration would appear to be the neoplastic and the degenerative. At the moment the former is the more fashionable, although it fails to explain why adenomata should appear with such frequency in the prostate at a particular time of life. The theory that the enlargement is due to degenerative changes in the gland furnishes such an explanation, and an additional argument in its favour is supplied by the close resemblance between the histology of prostatic enlargement and that of the female breast at the menopause, a resemblance first noted by Mr. Henry Wade. Indeed, the microscopic appearance of the enlarged prostate is so similar to that of a chronic globular mastitis that it can only be distinguished from the latter by its characteristic corpora amylacea. Moreover, Mr. Kenneth Walker, in his Hunterian Lecture seven years ago, drew attention to the fact that prostatic enlargement is almost invariably associated with signs of degeneration and involution in the whole of the genital tract. These, he suggests, are indicative of a male climacteric, with its accompanying symptoms due to an unstable endocrine balance.

Not only is the cause of prostatic enlargement obscure, but doubt exists as to the structures involved. In the opinion of many Continental writers, notably those of the French school of urology, the condition is due to overgrowth of the various submucous glands situated in the prostatic urethra and around the neck of the bladder. According to this theory the prostate itself takes no share in this new formation beyond becoming compressed and atrophied around it. This diversity of opinion concerning not only the pathology, but the anatomy, of prostatic enlargement is probably due to the fact that we are dealing here with more than one pathological entity. Under the heading of prostatic enlargement have been placed cases of enlargement of the prostate itself, hypertrophy of various groups of submucous glands, inflammatory conditions accompanied by fibrosis, degenerative changes, and cases of true adenoma formation. It is only lately that any attempt has been made to differentiate between these various conditions, and much careful work, both in the laboratory and in the operating theatre, will be required before this can be done with any degree of accuracy.

When we turn to the question of treatment we find, happily, a greater unanimity of opinion. Where differences occur they concern technique rather than first principles. The indications for operation have been defined with some exactitude. These indications rest on the presence of signs of obstruction rather than on the presence of enlargement itself. It is realized that a considerable degree of enlargement may exist without any interference with micturition, and the majority of clinicians are prepared to adopt the expectant policy in such cases. Professor Grey Turner, in the interesting paper published this week, gives concrete examples of patients who have lived comfortably for many years with enlarged prostates. At the same time it must be admitted that certain authorities consider that the risk of such prostates becoming the seat of malignant disease justifies their removal. The fact that this risk can be assessed at a figure in the neighbourhood of 14 per cent., and that the mortality rate of prostatectomy throughout the country cannot be very much below this number, constitutes a serious argument against such a tenet. But, as has already been said, the chief divergence of opinion at the present day is that which concerns operative technique, one school of surgeons inclining towards the old blind method of enucleation, and the other towards the open operation advocated by Sir John Thomson-Walker. On theoretical grounds the latter would appear to be the better procedure, since it brings prostatectomy into line with the majority of modern operations performed under ocular control.

Next to renal failure, the sequelae most to be feared after prostatectomy are haemorrhage, sepsis, embolism, and obstruction. By bringing the field of operation under direct vision much can be done to avoid these unfortunate accidents. Bleeding points can be ligatured, torn fragments removed, and the prostatic bed treated according to general surgical principles. At the same time it must be confessed that the open operation, although it may reduce the risk of haemorrhage, of severe infections, and of post-operative obstruction, provides no certain guarantee that such complications may not occur. Moreover, the additional time required presents a serious disadvantage in certain cases. For this reason it would seem that the solution of the problems lies not in a blind adherence to one or the other method, but in a nicely balanced judgement that shall enable the operator to adopt one method for one type of case and another for another. It is the judgement he shows in the pre-operative and post-operative care, and the suiting of his technique to the requirements of each particular case, that determines the success of the prostatectomist. Manipulative skill can have little effect on his mortality rate if this judgement be lacking. Herein lies the

explanation of the wide divergences that are found in the death rate of prostatectomy performed in different hospitals and by different surgeons. Any operator of average skill can enucleate a prostate, but only those who have acquired judgement and experience in this type of surgery can do so with any degree of safety. It is for this reason that papers contributed by those best fitted to write on this subject are of such especial value.

DEMENTIA PRAECOX.

"CONTINUITY in change and change in continuity." Burke's political aphorism may be fittingly applied to recent developments in psychiatric science, especially in regard to the changing attitudes towards that large group of the psychoses formerly termed dementia praecox and now more generally styled schizophrenia. When, some thirty years ago, Kraepelin introduced the appellation "dementia praecox" into the literature of psychiatry, a sudden clarification was brought about in our ideas of mental disease. In vain had Clouston adumbrated his adolescent insanity, which in many respects foreshadowed the Kraepelinian hypothesis. In vain also had Morel described as "démence précoce" cases illustrative of a profound degeneracy of constitution. Neither of these concepts had caught on. Clouston, indeed, had drawn a picture of certain patients, "unusually stupid-looking, lethargic, very dirty in habits, unobservant, uninteresting, silly, with a blank inexpressive face, a listless dull eye, and a flabby muscular system," as simulating secondary dementia, and, indeed, when they lived long enough, as constituting it; but his "adolescent insanity" failed where two Latin words later succeeded in holding the medical imagination. With Morel the case was different. For long the French school had been intrigued with the idea of a constitutional degeneracy in the sense that future generations became unable to hold their own in the struggle for existence and finally perished; and it was not with the object of demonstrating the dementia into which such cases finally succumbed that Morel drew his clinical picture, but rather with a view to illustrating still further examples of the degeneracy concept. Kahlbaum's description of katatonia was a distinct advance; and this group was incorporated by Kraepelin in his more comprehensive term. Kahlbaum and Hecker's earlier attempt to designate as a separate clinical entity an adolescent psychosis of deterioration, which they termed "hebephrenia," was also not to survive save in the wider Kraepelinian synthesis.

Illuminating as the Kraepelinian nomenclature has been proved to be, it is more than doubtful if the term "dementia praecox" will survive. A recent symposium on schizophrenia,[1] with dementia praecox as its subtitle, contributed by numerous authors to the Association for Research in Nervous and Mental Disease in New York, shows clearly the recent reaction to Kraepelin's terminology and the reasons for this. Dr. C. Macfie Campbell, professor of psychiatry in the Harvard Medical School, referring to the influence of Kraepelin in making the outcome of the psychosis a basis for its classification, considers that the use of this term has done serious injustice to many patients, and "both in physician and nurse it has tended to paralyse therapeutic effort." He expresses his satisfaction that "the conception of dementia praecox is loosening its grasp on the psychiatric world, allowing physicians to come to the complex clinical material with open minds and free from a rigid schema with the subtle suggestion of an impersonal disease process, running its insidious course regardless of the life situation and of the personal problems of the individual." It may here be questioned whether a name can exercise so great a tyranny, whether the mere categorizing of a syndrome, admittedly in fatalistic terms, can have so potent an effect for evil. Therapeutic effort is not withheld in cases of general paralysis of the insane; and it is hardly possible to believe that if the disease had never been called by any other name than dementia paralytica it would necessarily have received neglect.

But it is not solely the fatalistic implications of the term "dementia praecox" that have led to its being supplanted by Bleuler's "schizophrenia"; we would rather say that this latter designation affords a wider survey of the personal problems of the patient, and in particular demonstrates his relationship to, or participation in, the larger category of the schizoid type. By applying Freud's psycho-analytic teaching to the study of dementia praecox Bleuler was enabled, in the first place, to show that one of the chief characteristics of this disease consisted in a splitting of the psychic functions, and, further, to demonstrate in everyone schizoid tendencies. The schizoid type is described as withdrawn, secluded, and not in normal effective *rapport* with the environment. In one of the contributions above referred to Dr. A. A. Brill recounts the case of a schizoid person who suddenly heard that his child had been injured and had died. He apparently showed no "affect" whatever, but about a month later fell into a state of deep depression. Asked by Dr. Brill why he was so calm on hearing of the accident, he answered that he did not like to hurt his wife. This affords an excellent example of the displacement of feeling with the outward indifference so characteristic of these cases. The term "apathy" has long been used to describe the emotional state of the schizophrenic. Many observers have been inclined to correlate the stupidity of countenance with an absence of mental activity. Such is, however, far from being the case. The countenance is a mirror wherein the expression of the emotional state is most easily read, but the countenance of a schizophrenic is often an utter blankness. Dr. H. S. Sullivan, *in his* contribution to the symposium, reaches the conclusion that "apathy and emotional disharmony of the schizophrenic patient are more a matter of impression than a correct evaluation of the inner experience of the patient." He refuses to accept the view that there is any genuine disharmony in the schizophrenic life, but would rather argue that there is disagreement between what the schizophrenic patient actually *thinks* and what he feels called upon to say.

Numerous highly interesting problems call for solution in the study of schizophrenic reactions; and their number and nature are largely the outcome of a new orientation called forth by the work of Bleuler and that of Kretschmer, whose studies of the relationship of personality and psychosis to body type have provided so fertile a field for research. Faced with the manifold perplexities offered by psychiatrical problems, the scientific observer can yet discern in the fluctuations of experimental examination, of clinical description and terminological designation, "continuity in change, change in continuity."

[1] *Schizophrenia [Dementia Praecox]: An Investigation of the Most Recent Advances, as Reported by the Association for Research in Nervous and Mental Disease. A Series of Research Publications.* Volume V. New York: P. B. Hoeber, Inc. (Med. 8vo, xiv + 491; 61 figures. 7.50 dollars.)

DIAGNOSIS OF EARLY PREGNANCY.

ANOTHER reputed test for pregnancy has made its appearance, based on the hypothetical existence of a specific hormone modification. We referred last summer (June 2nd, 1928, p. 952) to A. C. Siddall's report of the discovery in the blood of a pregnant woman of a hormone which caused enlargement of the uterus and breasts. Now, in the *Zentralblatt für Gynäkologie* for January 5th (p. 15), S. Aschheim describes the technique and results of the test which he has devised with B. Zondek. He states that in pregnancy there are to be found in the urine very large amounts of the hormone of the anterior lobe of the pituitary body. To five infantile mice weighing from 6 to 8 grams are given subcutaneous injections of the morning urine of the patient to be tested, the amounts ranging from 1.2 to 2.4 c.cm. An injection of the urine is also made into a castrated mouse in order to test by the Allen-Doisy method the presence of ovarian hormone; this however, appears in the urine in pregnancy later than the pituitary hormone, and is found also in the urine of non-pregnant subjects. After one hundred hours the animals are killed and the ovaries are examined with the naked eye or with a pocket lens, or, in some cases, by serial sections. Aschheim describes threefold changes in the ovaries resulting from the action of this pituitary hormone: (1) the production of large follicles, which may ripen and burst; (2) bleeding into the proliferating follicle; (3) luteinization of the theca and granulosa cells of the follicle, with formation of corpora lutea atretica. The last two of these findings signify a positive result of the test; follicular enlargement, although denoting presence of the hormone, is apparently induced by such quantities as are present in the urine of a small percentage of non-pregnant patients. Before the animals are killed the presence or absence of vaginal swelling, hyperaemia, and discharge such as accompany oestrus is noted; these signs are attributed to ovarian hormone, in the production of which the hormone of the anterior lobe of the hypophysis (in the view of Zondek and Aschheim) acts as a stimulant. The reliability of this test in the detection of early pregnancy appears, in the hands of Aschheim, to have been considerably greater than that of the other biological tests for pregnancy which have been described from time to time. In 318 urines from non-pregnant female patients the test was negative in 315; in 15 from male patients, negative in 14. Among 295 tests in pregnant women there were only 7 negative results; 56 cases of pregnancy of five to six weeks' duration gave 54 positive results, and 68 pregnancies of seven to eight weeks' duration 66 positive results. The earliest diagnosis made was in the case of a patient with thirty-three days' amenorrhoea. About one week after labour the reaction is no longer given by the urine, and after the death of the foetus in the uterus the reaction is said to disappear in about eight days. Twenty-two cases of tubal pregnancy were tested; 16 gave a positive result, and the remainder—in which foetal death had occurred some time previously—a negative result. Two cases of hydatidiform mole gave positive results, and in one a relatively small amount of urine (0.05 c.cm.) sufficed. Aschheim mentions a case of chorion epithelioma following hydatidiform mole in which the Zondek-Aschheim test was positive twenty-one months after hysterectomy, when nephrectomy was performed for metastasis; the hormone persisted in increasing concentration in the urine until death. It may be inferred that not the presence of the living foetus, but that of living chorionic epithelium, is essential for a positive test; it is recommended that after the occurrence of hydatidiform mole the Zondek-Aschheim test should be performed at intervals for some months at least, in order to detect the possible presence of chorion epithelioma. In the same issue of the *Zentralblatt* (p. 22) L. Kraul and J. Rippel report their experience of the Zondek-Aschheim test in thirteen very early pregnancies, including one in which there had been eight days' amenorrhoea only, and eight of which were subsequently shown to be pregnancies of four weeks' duration; all gave positive results. In two cases a positive test led to the correct diagnosis of early pregnancy in myomatous patients in whom amenorrhoea might, it was thought, indicate either pregnancy or approach of the menopause. In ectopic pregnancy the result of the test depended on foetal survival. A positive reaction was given in a case of hydatidiform mole in which no foetus was found. Odescalchi has obtained good results in thirty cases of pregnancy in the later stages (see *Epitome*, February 2nd, para. 119). H. W. Louria and M. Rosenzweig record briefly in the *Journal of the American Medical Association* (December 22nd, 1928, p. 1988) the employment of this procedure in 132 cases. Their percentage of error was about 5, and they are confident that this can be reduced. The practical importance of such a test, if reliable, needs no emphasizing, but experiment on a large scale is necessary to establish its clinical value. We therefore call the attention of our readers to Professor R. W. Johnstone's letter on page 264, in which he explains how general practitioners can co-operate with him and his colleagues in the Animal Breeding Research Department of the University of Edinburgh by sending samples of urine for testing in this way. In view of the diagnostic value of information as to the existence of pregnancy in certain obscure gynaecological cases, the fees proposed for this examination seem very moderate. Professor Johnstone may reasonably expect to receive adequate supplies of material to enable him to reach a definite conclusion as to the clinical utility of the Zondek-Aschheim test.

INFLUENZA.

IT is already evident that the current recrudescence of influenza is more serious than that of last year, but whether the total mortality will attain that of the year 1922, or (as is perhaps more likely) not substantially exceed that of 1927, is a question which cannot be answered with any real plausibility. In 1922 the quotas of weekly deaths increased at first slowly, so that the rate of increase was greatest when the epidemic had been in progress several weeks. In 1927 the rate of increase was greatest early in the course. This year the deaths reported from the great towns of England and Wales have, so far, been increasing at an advancing rate, so that it will not surprise us if this week's figure is considerably larger than that of last week. An interesting feature of the statistics is that the ratio of deaths in one week to notifications of primary pneumonia of the previous week is very much smaller than in 1922, and, on the whole, smaller than in 1927. For instance, last week the deaths in the great towns were 521, the notifications of pneumonia of the previous week 1,864; in the week of 1922 with the nearest number of deaths—namely, 418—the figure for pneumonia was 1,157. Of course, the deaths and notifications do not relate to the same populations, the latter covering a wider area; but, if we postulate a uniform standard of notification, the suggestion is that this prevalence is of a milder type than that of 1922. That, in general, the prevalence is mild seems to be confirmed by clinical reports from all parts of England and Wales. So far, at least, Liverpool and Manchester, although suffering more than London, have been less hard hit than Glasgow. The age distribution of the deaths is of the usual type—that is, showing a predilection for those past middle age. The recrudescence of 1922 was

widespread in Western Europe; thus, in London the deaths increased from 1,024 in 1921 to 2,600 in 1922; in Amsterdam from 25 to 276; in Paris from 145 to 517; in Berlin from 669 to 1,891; and in Copenhagen from 21 to 198. In American cities, which have suffered severely this winter, the upward movement was then less notable; thus, in Chicago there were more deaths assigned to influenza in 1922 than in 1921—namely, 317 against 114; in 1923 there were 428, while in 1920 there were 2,037.

THE COLONIAL VETERINARY SERVICE.

EIGHTEEN months ago Mr. Amery convened a committee, under the chairmanship of Lord Lovat, to consider the reconstruction of the veterinary services in the dependencies which were not self-governing. The report of this committee, which was presented to Parliament at the end of January, draws attention to the important work which can be done in the tropics by an efficient veterinary organization. Not only are there many pressing questions concerning the health and disease of stock and draught animals to be considered, but many equally vital problems of human disease can only be solved by the closest association between medical men and veterinarians. Moreover, increased prosperity in agriculture, the staple industry of our colonies, means increased revenue, which in turn will provide the ways and means of improving human health and hygiene. The committee considers that the veterinarian should concern himself with animals in health even more than in disease, and consequently recommends that the name "Veterinary Department" should be abolished in favour of that of "Department of Animal Health." In order to fulfil the important functions of such an organization it is recognized that more and better men must be attracted into the profession, and to this end it urges the creation of a unified Colonial Veterinary Service, with salaries commencing at £600 per year and reaching a possible maximum of £3,000 in special cases. This unified service would benefit both large and small colonies alike. Young officers would be attached to a large colony to learn the elements of their work, and from this young personnel the single animal health officer required by the smaller colonies would be drawn; in these he would learn to assume responsibilities and to undertake tasks of organization and administration which would be invaluable both to himself and the Colonial Governments when later he was posted to a larger unit. To assist in the recruiting of suitable candidates to the profession a temporary scheme of scholarships is proposed whereby graduates in pure science may obtain veterinary qualifications and veterinarians may take science qualifications. To supply the field workers and administrators with the material wherewith to carry out their duties and to co-ordinate their efforts, several important proposals are put forward. These include the appointment of an adviser in animal health at the Colonial Office with strong advisory committees to assist him; a school of tropical veterinary medicine would be established at home, and a central research institute abroad. The report is the work of statesmen, lay administrators, medical men, and veterinary scientists, and its conclusions are unanimous. Its proposals are far-reaching in their scope, and their effect, if they are put into practice, will be to place the solving of the problems of animal health in the tropics on a thoroughly satisfactory basis. Our readers do not require reminding how intimately these are bound up with problems of human tropical medicine and hygiene. We hope that every effort will be made to develop these proposals, and to establish a service which has been long an urgent demand; such a service could not fail to have the most beneficial effects on the general health and prosperity of the empire.

POPULAR DIETETICS.

IN recent months the Royal Indian Agricultural Commission, in its illuminating report, laid great stress on the importance of nutrition in relation to the progress and happiness of the people of India. Although it is probably correct that the initial problem for many millions in that country is to obtain enough to eat, yet "the simple truths of nutrition and how to make the best use of such foodstuffs as are obtainable" must be taught to those who are sufficiently educated to understand. Nothing, it seems, more impressed the members of the Commission during their tour through India than the evidence of Colonel Robert McCarrison, I.M.S., and the visit they made to the Pasteur Institute, Coonoor, where his elaborate experimental work is carried out. In response to a widespread demand for further information regarding food, received from "missionaries, planters, school teachers, child welfare workers, and others throughout India," Colonel McCarrison has produced a delightful little book on *Food*,[1] dedicated to the "Children of India." In the course of twenty-two lessons the author tells young people what to eat, why they eat it, and explains how the greatest single factor in the promotion of good health is good food; he presents in the simplest possible language the results of twenty years' work. The descriptive analogies of the reactions the organs of the body make to various foodstuffs constitute word pictures which cannot fail to attract the attention of every intelligent child; and education authorities, even in England, will find it difficult to discover a more suitable book for adoption as a school reader. The book is certain, however, to command an even wider interest, for it presents in the most explicit terms all the adult lay reader requires to know about the various components of a diet. Probably the useful tabular statements at the end of the book, giving among other things the vitamin contents of common food articles, were included because the author himself envisaged a larger circle of readers than he originally intended to cater for. Royalties on the sale of this little book are devoted to certain Indian charities.

FLORENCE NIGHTINGALE ON THE STAGE.

As its title implies, *The Lady with a Lamp* is founded on the life of Florence Nightingale, but the author, Captain Reginald Berkeley, has avowedly used "a certain dramatic licence" in depicting her personality and some of the leading features of her career. The programme explains that it is "an imaginative treatment of a psychological theme," and as such this play is drawing large and appreciative audiences to the Garrick Theatre. Joseph once told Miss Nightingale that it had been her fate to become a legend in her own lifetime. Sir Edward Cook in his admirable *Life*, did a good deal to correct the popular romantic notion. He showed that "the real Florence Nightingale was very different from the legendary but also greater." Readers of large two-volume biographies form, however, a small section of the public and it remained for Mr. Lytton Strachey, in *Eminent Victorians*, to correct the notion still more drastically, and perhaps to build up another legend. Captain Berkeley has, we think, tried to steer a middle course in his interpretation of Miss Nightingale's character and ideals. He recognizes that it was as administrator and reformer more than as angel that "Santa Filomena" showed her special gifts, and he understands the significance of her early days in relation to her lifework as a whole. In order to make the point that, with all her clear-headed realism, she was "an intensely human woman with [illegible]

[1] *Food*. By Robert McCarrison, C.I.E., M.D., LL.D., F.R.C.P., Lieutenant-Colonel I.M.S. Calcutta and London: Macmillan & Co., Ltd. 1928. (Cr. 8vo, pp. 115; illustrated. 1s.)

passions and desires common to all vivid personalities," he introduces a love interest into his play, but does this with so much discretion that our sense of probability is not offended. He is fortunate in the actress who takes the leading part. Miss Edith Evans brings great intelligence and sympathy into her interpretation, and the way in which she matures and ages from act to act is a triumph of restrained characterization. Of the other players many deserve praise, but special mention should be made of Miss Muriel Aked as Mrs. Nightingale, Miss Gwen Ffrangcon-Davies as Elizabeth Herbert (afterwards Lady Herbert of Lea), and Mr. Henry Oscar as Dr. John Sutherland. Mr. Eille Norwood as Lord Palmerston is good, but rather unlike our idea of "Pam." The last scene—the bestowal upon Miss Nightingale, aged 87, of the Order of Merit—is an elaboration of Mr. Strachey's closing theme based on the words, "Too kind, too kind!" Altogether this is a very agreeable and thought-provoking play, of peculiar interest to medical men and women. Once again intelligent playgoers are under a debt to the Arts Theatre Club Production.

DOCTORS' HANDWRITING.

THE reproach of illegibility has long attached to the handwriting of doctors: but the guilt, if guilt it be, appears to be shared by many others. In business houses, for example, it is stated that the financial loss from errors due to bad handwriting amounts to a very large sum each year. The fact that elementary school children write more clearly than those attending secondary schools suggests that one reason for bad handwriting is the extension of the school curriculum to include an increasing number of subjects, a factor which would operate with greater effect in secondary than in elementary schools. The cultivation of good handwriting depends a great deal on the amount of time that can be devoted to it. In a leisurely civilization fine penmanship is usually held in high esteem. When life ambles gently in a "green and pleasant land" the person of culture may find time to devote himself to producing a beautiful script. But with the speeding up of life has come a shifting of cultural values; with so much else to do and learn calligraphy has receded in importance. Only in elementary schools, it appears, where the syllabus is not yet overburdened, and the child is not forced to take notes at lightning speed, is there time to build up a legible copy-book script. Is it possible that snobbery may some day compel the cultivation of a vile fist as the distinctive mark of social superiority, much as the droppin' of the final "g" was once imposed in certain huntin' and shootin' circles? With the proved prevalence of bad handwriting, however, it is interesting to consider why popular fancy has chosen for special reprobation the illegible script of the doctor. It may be that the doctor really writes worse than other people. He has, after all, spent five years or more in a course of study which calls for perpetual note-taking—in what other faculty can one find a range of subjects so extensive and so difficult as his? And if as a student who must master all this knowledge he cannot give much thought to mere legibility of script, what of the time when he is burdened with the cares of a busy practice? Life is short, art is long, and he writes his letters and prescriptions as swiftly as possible. The explanation may not, however, be so simple. Perhaps, in fact, the doctor's script is no worse than that of any other professional man, but patients given to the pastime of scrutinizing prescriptions, convinced, moreover, that the doctor's scrawl is designed to keep secret the contents of these documents, are more likely to attribute their failure to decipher what is written to the doctor's illegibility than to their own ignorance of dog Latin and pharmaceutical terminology. It is, after all, a commonplace that in the clearest and most beautiful script unfamiliar words are more difficult to read than those which are familiar, and the average prescription teems with words which, even when spelt out in full, are beyond the range of the average layman's vocabulary.

GIFT FOR MEDICAL EDUCATION.

As a thank-offering for his escape with slight injuries in a motor-car accident last December, Lord Beaverbrook placed at the Prime Minister's disposal the sum of £22,800, expressing a wish that his gift should be distributed widely for the benefit of medical education in this country. It has now been announced from Downing Street that the Royal Society of Medicine will receive £2,600, and each of the following institutions £1,000: the Royal College of Physicians, the Royal College of Surgeons, the Medical Faculties of the Universities of Oxford, Cambridge, London, Durham, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, St. Andrews, Glasgow, Aberdeen, Edinburgh, and Wales, Epsom College, the Cancer Hospital, and the Queen Charlotte's Hospital National Mother-Saving Campaign. The grant is to be applied in each case for special purposes beyond the capacity of the ordinary income of the institutions—for example, on studentships, research, and contributions to scientific equipment.

WE much regret to announce the death of Sir Alexander Ogston, K.C.V.O., LL.D., M.D., Emeritus Professor of Surgery in the University of Aberdeen, and Extra Surgeon to H.M. the King in Scotland, who presided over the Annual Meeting of the British Medical Association at Aberdeen in 1914. A memoir, with portrait, will appear in our next issue.

THREE lectures, entitled "*Thirty years' experience of* industrial maladies," will be delivered by Sir Thomas M. Legge, M.D., before the Royal Society of Arts, John Street, Adelphi, on February 18th and 25th, and March 4th, at 8 p.m.

THE KING'S ILLNESS.

WHILE convalescence has not yet begun, and cannot be expected to begin for several weeks after removal to the seaside, His Majesty's condition continues to improve little by little. There is a slow but definite increase in strength, and even a slight gain in weight. The King has been able to sit up for a short time on two occasions, with benefit to his health and spirits.

When the decision was first made to employ ray therapy in the treatment of His Majesty the choice of method was determined by two considerations. For clinical reasons the exposures could be made only for short periods of time, and applied only to small areas of the body surface, in order to reduce the degree of disturbance to a minimum. It was accordingly decided to use the mercury vapour lamp, with the object of stimulating parathyroid activity, adjusting calcium metabolism, rectifying the leucocyte count, and raising the bactericidal power of the blood. At the more serious stage of the illness this type of lamp, which emits a rich supply of ultra-violet rays, was therefore judged to be the method of choice. There is reason to think that the progress that occurred during the period of application of such measures was in part due to them. The improvement now attained renders possible treatment by the carbon arc, with its more penetrating luminous rays, whose energy, it may be hoped, will become converted to the use of the body, and thus favour the action of sea air, sunlight, and change of scene.

England and Wales.

The Mayor of Bath.

THE death of Alderman Cedric Chivers, mayor of Bath, which took place on January 30th, will recall to those who attended the Annual Meeting of the British Medical Association at the West of England spa in 1925 one of the most generous civic hosts whom it has been the fortune of the Association in its annual travels over to meet. Alderman Chivers actually took office as mayor that year, for the second time, in view of the visit of the Association, and not only in the exercise of a princely hospitality on the occasion itself, but in much trouble and care over the arrangements long beforehand, he played a very large part in making the meeting memorable. His great reception will not readily fade from the memory of the 2,500 guests who attended. A large reception hall, with annexes, was built in the Abbey churchyard, the banks of the neighbouring Avon were illuminated, and a succession of entertainments quite out of the ordinary were provided. Alderman Chivers was no orator, his speeches were as a rule models of brevity, but they breathed his love for Bath, which was his native town, every stone of which he knew, and the glories and traditions of which he did not a little to maintain. Last year also, when the Conference on Rheumatic Diseases met in Bath, Alderman Chivers again provided generous hospitality, though he was too ill himself to make an appearance. It was the same with all the various conferences visiting Bath. His long mayoralty—six years—in which, being a widower, he persuaded Madame Sarah Grand, the author, to be associated with him as mayoress, will remain a distinctive episode in Bath's great annals. He was at the head of every movement for beautifying the city and removing any reproach in its housing. One other great achievement of his was the establishment of the orthopaedic department of the War Hospital at Combe Park. Needless to say, he was a man of great wealth. His fortune was made in the unusual sphere of bookbinding, an art which he had revolutionized by a new method of stitching and also by a new decorative process for choice books; but he had in addition many generous interests in art and literature.

Maternal Mortality Problems.

Mr. Neville Chamberlain, the Minister of Health, was the principal guest at a luncheon given at Salters' Hall, London, on January 29th, by Lady Howard de Walden, in connexion with the national mother-saving campaign promoted by Queen Charlotte's Maternity Hospital. In the course of his speech Mr. Chamberlain said that the country was spending about £2,000,000 of public money every year on maternity and child welfare services, and a further large sum was being spent out of voluntary resources for the same purpose. The figures of infant mortality showed a remarkable drop since this service was initiated, but maternal mortality for the last twenty years had remained about the same—namely, about four deaths per 1,000 births. In spite of all the advances in medical and surgical science, in spite of all the money spent on ante-natal and post-natal clinics, in spite of all the propaganda that had gone on, and the improvement in the training of midwives and the practical disappearance of "Mrs. Gamp," they had not been able to budge this obstinate figure. Mr. Chamberlain then said that the first thing to be done was to find why they could not get this figure down. It was known that one of the principal causes was puerperal infection, but they did not know how that arose, and they therefore could not prevent it. He then referred to the inquiry recently instituted by the Ministry of Health, saying that he had enlisted the services of the local authorities and the medical profession in an endeavour to secure a report on the circumstances of every maternal death, and had set up a strong committee of experts to examine the information secured. One of the difficulties was that these cases of puerperal infection were scattered so that no one investigator had in his hands sufficient material for a continuous and intensive study of the particulars. He was therefore delighted to learn that Queen Charlotte's Hospital proposed in its new scheme, to which reference was made in our last issue (p. 220), to provide an isolation block solely for such cases. That was a lead given by a voluntary hospital which, he thought, showed the direction in which they must work if they were to obtain substantial and valuable results from research into the cause of puerperal fever. Summing up, he said that they wanted more ante-natal and post-natal clinics, more beds in maternity hospitals and homes for difficult and complicated confinements, more specialists in obstetrics to attend those complicated cases, and more skilled nurses for them when they were confined in their own homes. Lastly, but by no means least, they wanted more education of the people as a whole so that they might realize the need for special care in maternity. In conclusion, Mr. Chamberlain referred to the recent establishment of a committee to investigate the training of midwives, and to the need for raising the standard among them. Mr. J. Gibson Jarvie, a member of the committee of management of Queen Charlotte's Hospital, said that it was intended to provide proper facilities for research.

Radiological Services at London Mental Hospitals.

The London County Council eighteen months ago authorized, as an experiment for one year, the employment as consultant of an expert radiologist in connexion with cases of illness among patients at the mental hospitals, at an inclusive fee of one guinea for each case reported upon by him, subject to an expenditure limit of £210. It is now stated that while the experiment has met the needs of the hospitals, the appointment of one consultant radiologist to act for all the institutions is no longer advisable, in view of arrangements which have been made between several of the mental hospitals and the general hospitals for the services of consultants on the staff of the latter to be available for the mental hospitals. It is therefore proposed, as a further experiment for twelve months, that the medical superintendents shall be authorized to utilize the services of radiographers on the staff of associated general hospitals for advice and assistance in the taking of difficult radiographs, and for assistance in reading radiographs, when necessary, at a fee (if required) not to exceed, as a general rule, one guinea for each case dealt with, and subject to a limit of expenditure for each mental hospital of twenty guineas—that is, £210 for all the hospitals together—for the twelve months.

Scotland.

Glasgow Relics of Lord Lister.

A FINAL meeting of the executive committee of the Glasgow Lister Memorial Fund was held in the City Chambers on January 27th, with the object of winding up the fund and discharging the committee. The Lord Provost, Sir David Mason, presided, and it was stated that the only matter which still required decision was the final destination of the various memorials of Lister and other relics illustrative of the evolution of surgery which the committee had acquired in the early stages of the fund with a view to their being preserved in the old Lister ward of the Royal Infirmary. Sir John Samuel, honorary secretary of the committee, submitted a report of the history of the fund, and said that the committee had been formed in February, 1912, when the movement to provide a memorial of Lister in Glasgow was inaugurated. It had been resolved at that time that the most appropriate monument to Lord Lister would be the formation of a Lister museum in the ward which had been used by him in the Royal Infirmary at the time when the first experiments with antiseptics were made. Negotiations were thereafter opened with the managers of the Royal Infirmary for the preservation of this ward, but it had been finally resolved that the ward should be demolished, and this was done, to the great regret of the memorial committee. The funds in the hands of the committee had thereafter been used for the erection of a statue to Lord Lister in the Kelvingrove Park. In view of the hope held out at the commencement of the committee's work that the Lister ward at the Royal Infirmary would be preserved, Mr. A. E. Maylard and the late Sir Hector Cameron had collected a large number of valuable articles belonging to Lord Lister or associated with his work. These had been deposited meanwhile in the Royal

Infirmary, and with the approval of the managers were placed in the central hall of the Pathological Institute under the care of Professor Teacher. In July, 1926, they had been lent to the Wellcome Historical Medical Museum in London to form part of an exhibition of relics in connexion with the Lister centenary celebrations in 1927. The question now arose as to their final destination. It was resolved that the relics should be presented to the University of Glasgow for permanent custody, but that if the University did not see its way to accepting the gift they should be offered to the Corporation for preservation in the Kelvingrove Museum. A vote of thanks was accorded to Mr. A. E. Maylard, who had acted as convener of the subcommittee that collected the relics, and as editor of the memorial volume on Lister.

University of Edinburgh.

The University Court of the University of Edinburgh, at a meeting on January 28th, with Principal Sir J. Alfred Ewing in the chair, approved an ordinance increasing the matriculation fee from £2 2s. to £2 12s. 6d. It is intended that the additional 10s. 6d. should be set aside for a special fund to be called the Physical Welfare Fund, and to be administered by the court. All payments from it are to be made with the object of promoting, directly or indirectly, the physical welfare of students of the University. The increase in the fee will take effect on October 1st next. At the same meeting Sir Alfred Ewing intimated his intention to retire from the principalship of the University on September 30th next. In his letter of resignation he stated that he had hoped to carry on his duties to the age of 75, the age limit fixed for principals of the Scottish universities, but that reasons of health had persuaded him to retire a year earlier. Before coming to Edinburgh Sir Alfred Ewing had a long experience, both as a teacher and as an administrator. After holding a professorship of engineering at the Imperial University of Tokyo, he was called to the professorship of engineering at University College, Dundee, and afterwards was appointed to the chair of mechanism and applied mechanics at Cambridge in 1890. In 1903 he became director of naval education under the Admiralty, where he remained until 1916, when he succeeded the late Sir William Turner in the principalship of the University of Edinburgh. During the war he acted as the head of an organization which worked on the interception and deciphering of enemy wireless messages. During his tenure of office as principal the University of Edinburgh has passed through a period of considerable development and expansion. Since 1916 thirteen new chairs have been founded, as well as a large number of readerships. The chief addition to the University has been that of the King's Buildings on the south side of the city, where chemical laboratories and, more recently, departments of natural history and animal genetics have been provided. During his period of office, too, negotiations were carried through which resulted in the admission of women to full privileges as students in the faculty of medicine. Two new degrees have been instituted in this period, that of Doctor of Philosophy and that of Bachelor of Commerce, and important affiliations have been concluded with the training college for teachers and the Edinburgh and East of Scotland College of Agriculture. The appointment of a successor is in the hands of the curators of the University, a body consisting of the Lord Provost of Edinburgh with three representatives of the Town Council and three members of the University Court.

Aberdeen Sick Children's Hospital.

The new buildings of the Royal Aberdeen Hospital for Sick Children were opened by Viscountess Cowdray on January 31st. This is the first of the institutions to be completed on the extensive Foresterhill site to the north-west of the city in connexion with the large joint hospitals scheme, in respect of which a sum approaching £400,000 has been collected for buildings and partial endowment. The cost of the hospital itself is over £100,000. In the immediate proximity the new Royal Infirmary buildings, of which the Prince of Wales laid the foundation stone on August 23rd last, are making rapid progress. The new hospital is laid out on 17½ acres of ground, and provides accommodation for 128 cots in nine wards. A large playroom, facing the south-west, fitted with vita-glass, is a new feature of the hospital, and the provision of large verandahs enables cots to be wheeled out into the open air in fine weather, so that convalescent children may enjoy as much fresh air and sunshine as possible. Ample lawn accommodation is also provided as a playground for children in a later stage of progress towards health. The x-ray room is believed to provide the most elaborate apparatus of its kind in the north of Scotland. Separated from the hospital is a substantially built nurses' home, towards the furnishing of which many donors have come forward with handsome gifts. Mr. Harvey Hall, chairman of the hospital directors, presided at the opening ceremony, and was accompanied on the platform by the Marquess and Marchioness of Aberdeen and Temair, and others. The chairman said that over eighteen years had elapsed since the directors issued their first appeal for funds to build a new hospital. With the erection of the new hospital the annual expenditure, which at present exceeded £8,000 per annum, would be largely increased; it would still be necessary to secure an endowment fund, and they trusted that the many subscribers to the building fund would help them to raise that endowment fund also. Lady Cowdray, in performing the opening ceremony, remarked that it was peculiarly fitting that in the reorganization of the whole hospital work of the city the children's part should come first, for theirs should be the longest span of life, and their care was the best insurance which could be had for the conditions and durance of life in coming generations.

Ireland.

Vaccination in the Free State.

DR. E. STEPHENSON, who is the chief medical officer of the Free State Department of Local Government and Public Health, recently stated that in general the vaccination laws were now being administered satisfactorily, and that the number of defaulters was being reduced. The procedure is that unless a child is vaccinated within three months from the date its birth is registered the parents or guardians become defaulters. The vaccination officer then serves notice on each defaulter, and, failing compliance with the law, legal proceedings are instituted. Very few instances have occurred in which the vaccination authorities failed to discharge their statutory duties and institute proceedings, and in those cases the central authority which supervises the administration of this law compelled them to take action. Some of the local authorities were showing great interest in vaccination, and frequent requests for information as to its effects were made to the department. Dr. Stephenson referred to the results obtained by vaccination in infancy in England, recalling the views expressed by the committee on this subject which made its report last year, and in conclusion said that there was ample evidence of a growing belief in the efficacy of vaccination in Ireland.

County Hospitals and their Equipment.

The Irish Medical Secretary of the British Medical Association recently informed the Dublin press—in connexion with a resolution passed at a recent meeting of the council of the Irish Medical Association referring to the deficient equipment of certain county hospitals—that many of the county hospitals were quite unfitted for the performance of important operations, and that the equipment was often not up to date. It was pointed out, however, that a number of the county hospitals were excellent in every respect, and that great credit was due to the health boards who had spent the money to make the hospitals efficient. It was only right, moreover, to say that the Department of Local Government was continually urging the improvement of county hospitals, and that the department had invariably sanctioned the expenditure of local funds for this purpose. The trouble was that the old workhouses were still used as hospitals, and in these the water supply and the sanitation was not always good. There were excellent hospitals, it was added, equipped in

a modern way, at Castlebar, Navan, Wexford, Croom, Limerick, Cork, and elsewhere, and the aim should be to raise the other hospitals to their standard of usefulness. The problem rested largely with the health boards, whose proposals for hospital improvement were always sympathetically and practically considered by the Local Government Department.

Medical Certificates and School Attendance.

At a meeting of the Strabane and Castlederg Regional Education Committee it was stated that the attendance of school children was on the down grade in the six counties. Criticism was expressed of charges being made for medical certificates, especially in the case of children of poor parents. It was, however, explained, on behalf of the Education Committee, that if parents satisfied the school attendance committee with a reasonable excuse there was no prosecution, but that many did not do so, and instead appeared before magistrates with doctors' certificates and secured the dismissal of the cases, which was regarded as unfair. It was decided to inform teachers that medical certificates need not be insisted upon if they were satisfied as to the children's illness.

Display of Medical Films.

A meeting of the Leinster Branch of the British Medical Association was held on January 24th in the hall of the Royal College of Physicians, Dublin, with Dr. M. R. J. Hayes in the chair. An invitation was extended to non-members and medical students to be present at the exhibition of medical films by the Kodak Company. The attendance was very large, and the display of films was followed with the keenest interest for almost three hours.

Correspondence.

DIAGNOSIS OF EARLY PREGNANCY.

SIR,—The occasional great difficulty and importance of making the diagnosis of early pregnancy are so well recognized that any diagnostic test that is said to be reliable calls for serious consideration and examination. The latest such procedure, the Zondek-Aschheim test, promises to prove itself reliable, for the results of those who have tried it extensively indicate only a 2 per cent. incidence of error;[1] it depends on the presence in the urine of the pregnant woman of a hormone, which the original observers believe to come from the anterior lobe of the pituitary body, and any theoretical doubts which may exist in the minds of some as to the identity of the hormone do not affect the validity of the test.

The only practical difficulty in the adoption of the test is the need of a suitable supply of test animals under the care of an expert. This difficulty has been overcome in Edinburgh by my colleague Professor Crew of the Genetics and Animal Breeding Research Department, and in Dr. B. P. Wiesner, Ph.D.Wien, a member of the staff, we have a distinguished expert with the available material.

May I therefore inform the medical profession through your columns that in order both to test thoroughly the reliability of the Zondek-Aschheim reaction, and at the same time to be of help, if possible, in difficult cases, Professor Crew and Dr. Wiesner are prepared and willing to employ the facilities of the department in regard to any specimen sent to it?

The test is said to be valid from fourteen days after the first missed menstrual period. All that is required is to send a few ounces of the patient's urine, with a covering letter containing the clinical data, etc., to the Animal Breeding Research Department, King's Buildings, University of Edinburgh. It is proposed to charge a modest fee of 5s. in each private case to cover the cost of animals and other material, and this fee will enable similar tests to be made for the reduced fee of 1s. 6d. in all hospital cases referred to the department. The result of the test will be notified by post to the sender about a week after the urine is received.

The help which the test has already afforded to me in several cases in the last three months leads me to believe that in throwing their facilities open to the profession in this country Professor Crew and Dr. Wiesner are offering us very great practical assistance, and I hope that many of my colleagues will take advantage of these arrangements.—I am, etc.,

R. W. JOHNSTONE.

Department of Midwifery and Gynaecology, Edinburgh University, Jan. 31st.

TREATMENT OF FRACTURES.

SIR,—In the *Journal* of January 19th (p. 117) you comment on the present position of the treatment of Pott's fracture, and in the same issue appears a letter from Mr. Muirhead Little on fracture clinics, in which Mr. Little says: "The crux of the whole fracture problem is made up of the lack of interest in fractures which is shown by many general surgeons."

In your article you refer to the publication of Mr. Harry Platt, and later on mention that Dr. Frank Dickson, in his recent paper, recommends immediate reduction of the fracture and the application of plaster-of-Paris. It happens that at a recent examination at the College of Surgeons a late house-surgeon of Mr. Platt's was asked by a surgeon in a senior position in one of the London teaching schools how he would treat a Pott's fracture. He replied that he would reduce it and fix it in plaster-of-Paris, and was met by the examiner's comment, "Let me tell you that plaster-of-Paris is not the way to treat a Pott's fracture."

At the present time almost every orthopaedic surgeon in the country uses plaster for this fracture, finding that it is impossible to maintain reduction of the posterior displacement by any other method, and this treatment is not new, but has been in use for a number of years.

How are we to progress in the treatment of fractures when the surgeons who are teaching this treatment and examining upon it in the ordinary pass examinations fail to keep in touch with the present accepted ideas of treatment? Mr. Muirhead Little quotes Professor Hey Groves as suggesting that the solution of the problem of fracture treatment may come by utilization of the municipal hospitals, and adding to their staffs and equipment. This would, no doubt, be an advantage from the patient's point of view, as the segregation of fractures in these hospitals would tend to raise the whole standard of treatment, but it might well prove a disaster from the point of view of undergraduate education. The large teaching hospitals have already lost the whole of the treatment of tuberculous disease. If steps are taken which tend to remove from them the routine treatment of injuries, a section of surgery which is of very great importance to the general practitioner will disappear from the ordinary experience of the medical student.

It is to be hoped that the threat of such a thing happening will induce the staffs of the teaching hospitals to organize their treatment of fractures on more rational lines.—I am, etc.,

R. C. ELMSLIE.

London, W.1, Feb. 4th.

ENLARGEMENT OF THE PROSTATE.

SIR,—Sir John Thomson-Walker, in his letter in your issue of February 2nd (p. 222), criticizing my article on "Some problems connected with benign enlargement of the prostate," takes me to task for not advocating his operation whole-heartedly, is then unable to decide what I do recommend, and finally infers (or so it appears to me) that I claim credit for the long incision in the abdominal wall he has "recommended so long and so often."

In the first place, the article was written with a view to calling attention to some of the problems connected with the etiology and treatment of the enlarged prostate, and not to specify details of technique and operative procedures, otherwise I would not have hesitated to give my

reasons for not seeing eye to eye with Sir John in the operation he advocates. He states that the digital examination of the prostatic cavity I advise is an unreliable guide to the necessity or otherwise for an open operation. To this I do not agree. Given a sufficiently delicate touch it is quite possible to feel long tags of mucous membrane, small adenomatous masses, partially detached layers of capsule, and an unduly prominent vesico-prostatic shelf. The control of haemorrhage by ligature and suture, which is one of the supposed advantages of the open operation, is by no means so satisfactory as it sounds.

Secondly, I was under the impression that the operation I advocated, but did not describe in detail for reasons already given, was perfectly intelligible, but as Sir John is unable to understand let me now make it quite clear.

The "prostate" is enucleated through a long incision in the abdominal wall and a small one in the bladder, the former being to permit of easy access to the gland and to dispense with the necessity for a finger in the rectum. The walls of the prostatic cavity are then carefully palpated; if they are smooth the bladder is drained with a large tube, but if they are uneven and contain irregular masses, etc., the bladder is opened widely and they are removed by "the method described and advocated for a number of years" by Sir John Thomson-Walker. The supposition that I apparently recommend a combination of two different operations is therefore correct. I trust this explanation will relieve Sir John's anxiety that I should not "have it both ways," and that I should not indulge in such feats of prestidigitation as to "have a finger in the rectum and avoid putting a finger in the rectum."

The closing sentence of Sir John's letter expressing his gratification that "Mr. Nitch should have adopted, or at least approved of, even part of the technique that I have recommended so long and so often" naturally gives me the greatest satisfaction, which, however, is tempered by regret that in mentioning the open operation in my paper the name of the originator was inadvertently omitted.—I am, etc.,

London, W.1, Feb. 3rd. CYRIL A. R. NITCH.

SIR,—I was interested to read Mr. Nitch's article on benign prostatic enlargement in a recent issue of the *British Medical Journal* and Sir John Thomson-Walker's letter with reference to it. While thoroughly endorsing Mr. Nitch's approval of the long incision, I am surprised at his advocacy of the gloved finger. The sense of touch is the sole guide in an ordinary prostatic enucleation, and should be helped in every possible way, not dulled by any intervening medium. Mr. Nitch admits that he relies on the sense of touch, and yet handicaps himself by wearing a glove. The careful methods of procedure which are essential to a successful enucleation are much easier with the bare finger, and the "prostatic relics," which are difficult to detect even without a glove, are infinitely more so with one. The introduction of sepsis need not be feared if reasonable precautions are taken as to the hand. As Sir John Thomson-Walker pointed out many years ago in this connexion, gentleness of manipulation is an important factor as regards asepsis; it is decidedly more practicable without a glove than with one. Needless to say, this is no attempt to minimize the advantage of gloves in other operations.—I am, etc.,

London, W.1, Feb. 4th. W. K. IRWIN, M.D., F.R.C.S.

SIR,—Since the forage treatment of the prostate introduced by Dr. Luys of Paris has hardly yet won a place in the current practice of urology it may be helpful for a medical man who has undergone it to record his personal observations. Information of this kind is more precise, and its interpretation more scientific, than that obtainable from a patient without medical knowledge.

I am 58 years old. My urinary trouble commenced some seven years ago; it grew progressively more pronounced, and became almost intolerable during the last two years. *Micturition*, at first slightly frequent, increased until it recurred every two hours; the interval was then reduced to every hour or even less. Thus, in the end, my sleep was incessantly broken by the need to urinate, and I was obliged to rise six times or more during the night. The stream diminished in volume and force; the commencement of micturition was delayed, the act became increasingly difficult, and the end was an uncertain dribble. Eventually it became extremely painful to urinate, and this pain, recurring so very frequently, caused a marked depression in my general state of health.

In August, 1928, I consulted a urologist in London, who diagnosed an enlarged prostate and advised prostatectomy. This clinical and cystoscopic examination was painful to the point of provoking an acute retention of urine, haemorrhage, and some hours of acute suffering. Being already very depressed and anxious about the consequences of an operation, I decided to go to Paris in order to ask Dr. Luys if it would be possible to obtain benefit from his method of "forage de la prostate." At the time when Dr. Luys examined me my residual urine was constant at 75 grams. The pain on micturition was becoming intolerable; the urine was cloudy, and contained *B. coli*, enterococci, and staphylococci. I was subject to attacks of urinary fever rising to 103° F., and my general state of health was much lowered. I had lost weight, and looked and felt ill.

On my entry into Dr. Luys's "Maison de Santé" I was first submitted to preparatory treatment, which consisted of the slow methodical dilatation of the urethra with curved steel sounds (Béniqué's), combined with frequent irrigations of the bladder. When my urethra had become sufficiently "broken in" Dr. Luys was easily able to carry out an endoscopic examination of the prostate with his direct vision cystoscope. He diagnosed a prostatic adenoma localized to the left lobe of the prostate and forming an extremely pronounced projection at the level of the neck of the bladder. This prominence crossed the middle line to such an extent that its convexity pressed on the almost normal right lobe. The prostatic adenoma was not more than 2 cm. long in the antero-posterior direction. Thus my prostate was small in volume, and, in these conditions, forage was clearly indicated. However, before undertaking this operation Dr. Luys deemed it indispensable to treat first my local and general state of infection. On the advice of Dr. Bécart a course of oral vaccination was begun by means of a stock vaccine, a suitable kind being the enteroxin Leclerc, which is a mixed bouillon vaccine containing 50 per cent. *B. coli*, 25 per cent. enterococci, and 25 per cent. staphylococci (method Gaehlinger-Bécart).

The next day my temperature fell to normal and remained there in spite of the different interventions practised. Examination of the faeces showed a very marked microbic flora, and a pure culture of the colon bacillus was isolated by Dr. Bécart, who prepared an auto-vaccine, which I took for forty days each morning on waking. From the beginning of this treatment I had no longer any fever. The forage was performed during a period of immunization which sheltered me from oscillations of temperature, except on one occasion on the third day after the first operation, when there occurred a rise to 102° F., quite transitory, and of no consequence. My general health had undergone a rapid transformation, and the serious features of my case had been cured without any untoward incident.

The first session of electro-coagulation took place on October 12th, 1928, and, although not of great intensity, I was struck by the volume of the sloughs which I eliminated after ten days. I experienced a very marked and rapid improvement in micturition; the frequency diminished, and I emptied the bladder much better, the residual urine now not exceeding 30 grams. The second electro-coagulation treatment was given on November 9th, and seven days later, while passing water naturally, I shed an enormous eschar, which made room for a stream of urine strong and full from beginning to end of the act. Micturition is now effected without delay and without pain, my bladder emptying itself perfectly since that time.

I have thus, by this intervention, obtained the result I desired—that is to say, recovered the normal function of my bladder without incurring the risks of prostatectomy. I therefore consider that whenever the case is indicated—that is, in all prostatic enlargements of small or medium volume—it is extremely advantageous for the patient to have himself treated by the method of forage in preference to prostatectomy.

Forage is a conservative operation, easily borne, and terminating in a cure. It is a delicate and difficult procedure, demanding a high degree of experience and expertness in the use of a very specialized electrical and urological armamentarium, but its lasting success is shown by the re-examination of numerous cases extending over many years.—I am, etc.,

London, W.C., Jan. 3rd. G. A.

ERYTHEMA NODOSUM.

SIR,—If I read the signs aright another spate of correspondence on erythema nodosum is imminent. Might I be allowed to outline a summary of the status of this disease? The supposed association with rheumatic fever dates back to Stephen Mackenzie, whose data and conclusions are to-day regarded as scanty and altogether erroneous. The association has been perpetuated partly by a faithful copying from book to book of Mackenzie's conclusions and partly by a confusion in clinical observation between the genuine joint phenomena in rheumatic fever and the arthritic pains and fascial soreness which are indeed common in erythema nodosum.

Priority for the notion that erythema nodosum may be the rash of an acute specific infectious disease belongs to Dr. Harrison, who was president of the Dermatological Society of London in 1900. But this conception was elaborated with considerable weighty personal clinical experience by Dr. Lendon of Adelaide, who invented the term "nodal fever," and published in 1905 a book with that title. There has been steady observation in support of this term ever since; and I, for one, always read with the greatest possible pleasure and interest the writings of Dr. Odery Symes.

But by far the most important of the clinical relationships of erythema nodosum is its association with tuberculosis. Scores of published cases make this association indisputable. Some people, with good reason, look upon erythema nodosum as a herald of tuberculosis. I believe that the opinion of those who have most experience is that about 20 per cent. of all cases of erythema nodosum are followed by tuberculosis within a few months: but some Continental and Transatlantic clinicians put this figure much higher.—I am, etc.,

The General Infirmary, Leeds, Jan. 28th. G. F. WALKER, Medical Tutor and Registrar.

X-RAY DIAGNOSIS.

SIR,—Dr. Vincent Norman refers, on February 2nd (p. 225), to the correspondence on this subject in the *British Medical Journal* during the closing months of last year. This discussion followed the joint meeting of the Sections of Surgery and Radiology at Cardiff, at which it fell to my lot to reply to certain criticisms made by Mr. Herbert Patterson. I took no part in the subsequent correspondence in your columns, as it seemed to me that no new points were raised.

Now Dr. Norman breaks fresh ground. He talks about "a general practitioner's point of view of one of the contestants." By this he means his own view, which he is perfectly entitled to state, and which is no doubt of great interest. But when he speaks of "the radiologist" he enters the region of concepts. It is possible to have a satisfactory concept of a horse, because all members of the species will, in given circumstances, behave in much the same way. It may even be possible to have some sort of concept of a general practitioner; his evolution has, at any rate, been going on for hundreds of years. But what of "the radiologist"? Are his specific characters fixed? I should say not; zoologically, he must be placed rather in a phylum than in a species or even a genus. In other words, radiologists differ. This is evident even from Dr. Norman's letter, in which the crimes of one are not those of another.

To deal first with what I think are genuine grievances: the general practitioner should certainly have the radiographs of his cases if he wants them. In most instances a careful report with, if necessary, key diagrams, should enable the practitioner to follow the radiological argument. The chief risk in sending films is that some practitioners discover in them all sorts of alarming abnormalities which have no real existence; when the films are handed on to patients the tale of these discoveries is endless. However, the advantages of sending films or prints outweigh the disadvantages, provided it is made quite clear that the radiological opinion is what really counts.

Then Dr. Norman complains that in another case the negative is discussed with the patient before sending it to him. As a general rule this should not be done. The only exception I know is in the case of suspected fracture. Here, when a patient is inclined to grumble at his doctor, the demonstration to him of an unfractured bone, or of a fractured bone in excellent position, may have a good effect in making him believe he has been well treated; or the demonstration of a terrible smash may warn him not to expect miracles from subsequent treatment.

Negatives other than fractures should never be discussed with patients; but is the patient to be told nothing as to the result of the examination? No general answer can be given to this question. The radiologist should not volunteer information. His formula should be: "I will send a report to Dr. So-and-so, and you will hear from him." But not every patient can be put off with this. Some say, frankly, "I am paying for this examination and I want to know." Some concession must be made in such circumstances. If nothing suspicious has been found, I see no objection to telling the patient so, at the same time emphasizing that a negative x-ray finding is not conclusive. If the x-ray evidence is positive and serious, if, for example, it reveals a probable neoplasm, it is my practice to say, if pressed, "Your doctor has been very wise to send you for this examination, which has given information which will be of great value in the future treatment of your case." One can always refuse to be more explicit on the ground that time is needed to study the negatives.

With Dr. Norman's other grievances I have personally no sympathy. He complains that when he sends a patient to be examined for possible neoplasm of the stomach it is irritating to be told that, in the radiologist's opinion, the trouble is merely indigestion. I am sure that in some cases these opinions are, so to speak, purely conversational. To use the words of Pooh-Bah in the *Mikado*, they "give an air of verisimilitude to an otherwise bald and unconvincing narrative." I have known myself volunteer the opinion that a patient was suffering from a sprained ankle simply because it seemed so brusque to say merely that there was no x-ray evidence of injury to bone!

But when these opinions are not merely platitudinous should they be frowned upon? Here we touch a vital point on which agreement is probably impossible. There is the practitioner who wants, as he says, a plain "Yes" or "No" to his question, and, like a cross-examining counsel, is much annoyed if he does not get it. He asks, Has this patient a gastric or duodenal ulcer? He does not want to be told "No, but he has old lung tubercle, probably active, which may account for the indigestion of which he complains." Does he even wish to be told "No, but he has a chronic appendix, or a pelvic caecum with a seventy-two hours' residue"? It is doubtful. Gentlemen who want a plain "Yes" or "No," if they exist in sufficient numbers, will get the kind of photographer-diagnostician they desire. But a full medical training would be wasted in such a case. Any competent x-ray sister at a large hospital could answer these questions.

Adapting the phrase of an eminent surgeon, I like to call myself a "physician practising radiology." It should be remembered that nearly all radiologists of fifteen or more years' standing are men who have had wide experience of general medicine. They were physicians before they were radiologists, and have maintained their interest in medicine as a whole. They cannot be expected to stultify themselves by a deliberate narrowing of outlook which they believe would be to the disadvantage both of patients and practitioners. Such a degrading limitation is not expected in other countries. For instance, in the United States a leading radiologist is—or was—the dean of the faculty of medicine of his university. In a recent address Mr. Sampson Handley suggested to radiologists that they had until now, of necessity, been too much preoccupied with technique, but that it was now time that they concerned themselves more with pathology and other more strictly medical problems.

One piece of practical advice I should like to give to such of my younger colleagues as aspire to work on these lines: remember that radiological reports are handed on from expert to expert, and often seen by the patient. Make them as restrained as possible, and, if you must indulge in hypothesis, let it be clearly indicated as such.

Then, if you have other more general views which you think it might be of advantage for the practitioner to know, embody them in a private letter.

To sum up, the demands made upon the radiologist by practitioners are very varied. Some look upon him as guide, philosopher, and friend; others regard him as a necessary evil, to be looked on with suspicion and rigidly kept in his place. Both will ultimately get the kind of service they deserve.—I am, etc.,

London, W.1, Feb. 2nd. F. HERNAMAN-JOHNSON.

SIR,—Is it not time to end the recent vogue of baiting the radiologist in the medical press? Dr. Vincent Norman's letter does nothing to encourage a spirit of co-operation between the general practitioner and the radiologist, and tends to foster irritation in both. His remarks are obviously based on particular instances in which the radiologist acted outside the scope of his own province. But why argue from the particular to the general?

Few radiologists of any experience give information on points about which their opinion has not been asked. Radiologists should not be asked to give a diagnosis. They should be given all useful information about the case, and *asked to provide further evidence on specified points*. If the term "*x*-ray diagnosis" could be purged from our medical literature and the term "*x*-ray evidence" substituted, there would be less heard about misunderstandings between radiologists and other medical men. If a radiologist refuses to let the general practitioner see the radiogram, or causes offence in any other way, the remedy is obvious and lies with the general practitioner, but it is hardly a matter for ventilation in the press.

There is no doubt that in most cases the radiologist *should not*, and in fact does not, discuss the negative with the patient. Occasionally, however, the patient demands to see the negative, and to have it explained. In these circumstances it is doubtful whether the radiologist has the right to refuse, as presumably the patient is entitled to know the result of an examination for which he is to pay.

It is to be hoped that Dr. Vincent Norman's letter will not provoke radiologists to retaliate by airing their private grievances in public, for no good can come of it. We need more co-operation and less recrimination.—I am, etc.,

London, W.1, Feb. 2nd. PAUL CAVE, M.B., B.S., D.M.R.E.

DIABETES WITH LOW RENAL THRESHOLD.

SIR,—I agree with Dr. Lawrence (February 2nd, p. 196) that a lowered renal threshold for glucose in diabetics is not as uncommon as published cases would appear to suggest; also, that it is a complication which may give rise to difficulties in treatment if the possibility of its occurrence is not borne in mind; but I should like to add that there appears to be a very definite chemical explanation of the condition in the majority of cases.

The detailed chemical analysis of the blood, as well as of the urine and faeces, I have been able to make in over *one thousand* cases of diabetes, has shown that a lowering of the renal threshold is usually associated with a subnormal percentage of calcium in the blood serum, and, as an increase in the calcium to the normal level has been found to be followed by a rise in the threshold, it would seem that a deficiency of calcium is the probable cause of the unusual permeability of the kidneys in the majority of cases. There is *apparently no etiological connexion* between the diabetes and the lowered threshold, as Dr. Lawrence rightly concludes, for I have met with examples where abnormal permeability, and an associated fall in the calcium content of the blood, developed some time after all hyperglycaemia and glycosuria had been fully controlled by diet or insulin. In my records there are, however, a few cases of diabetes with a low threshold in which analysis of the blood showed a normal calcium content, so that abnormal renal permeability for glucose may evidently arise from more than one cause.—I am, etc.,

London, W.1, Feb. 3rd. P. J. CAMMIDGE.

TONSIL AND ADENOID OPERATIONS.

SIR,—I should like to state my experience with the La Force tonsillectome. In common with Mr. Lindley Sewell, who first demonstrated to me the method of use and advantages of this instrument, I have employed it for the last eighteen months, and have practically discarded all other methods in its favour.

As any user of any form of guillotine will acknowledge there are certain tonsils which can only be removed by dissection, but whenever a guillotine can be employed successfully the "La Force" can also be used with the same success. The essentials of a successful tonsillectomy are: (1) complete enucleation; (2) freedom from haemorrhage; (3) absence of trauma and injury to the faucial pillars and soft palate; and (4) freedom, as far as possible, from deformity after the operation area has healed.

I have used the La Force instrument in 329 cases, and in that series have only had one where it was necessary to take any measures to arrest haemorrhage. This was in a woman, aged 27, whose tonsillar artery had to be clamped and ligatured. It is not an easy instrument to use at first, and for that reason my last 150 cases or so have shown much better results than the first; this I attribute to greater familiarity with the instrument and also to having increased the time of compression with the haemostat. The very great majority of cases have been absolutely bloodless, no haemorrhage occurring at the time, and none noticed later by the patient or nurse in attendance. Where post-anaesthetic vomiting has taken place no blood has been present in the vomited material.

Since there is no need to make compression on the tonsillar fossae, a marked feature in cases operated on by this method is the absence of sore throat following removal of the tonsils. For its successful use *two factors are* needed: (1) The services of a skilled anaesthetist; and (2) familiarity with the instrument. It seems to me that any method capable of producing such satisfactory results is worthy of a trial, yet if the views expressed by Mr. Aldington Gibb (January 19th, p. 132) find general acceptance no new methods will ever be tried, and all advances in surgical technique will come to a standstill.—I am, etc.,

Manchester, Jan. 21st. FRANK G. WRIGLEY.

SIR,—The problem of haemorrhage after tonsillectomy is not quite such a simple matter as some of your correspondents would make it appear.

I had a case, within the past fortnight, of a young woman, aged 30, whose tonsils I removed by gauze dissection under the critical eye of her own medical attendant. The tonsils peeled out without difficulty, and were removed quite completely. I packed each tonsil bed with cotton-wool for a minute or two—as I always do nowadays—immediately the tonsil was removed. After removal of the cotton-wool one side still bled smartly, so I picked up the bleeding vessel and tied it off with a ligature; *the other side did not bleed at all when the cotton-wool was removed, so of course* no ligature was applied. The patient's *doctor* and I satisfied ourselves that both tonsil beds were completely dry before the patient left the operating table. In twenty-four hours I was called to the patient because of severe haemorrhage from the side which was not tied; an injection of morphine and the application of hydrogen peroxide on swabs had had no effect, but after a good deal of trouble the haemorrhage was stopped, the blood-clot having been cleared out, cotton-wool soaked in haemoplastin packed in two or three times, and morphine given. (If this had not been effective I would have taken the patient back to the theatre and tied the blood vessel under an anaesthetic.) All went well for a week, when I was called to the patient again because of severe haemorrhage *from the side which had been tied at the operation*. The patient said that the bleeding was quite as severe as it had been from the other side; the injection of 1/4 grain morphine sufficed, however, to control this haemorrhage.

I said to the patient that obviously her blood was *deficient in* coagulating power; but she told me that she had had some teeth out six weeks previously, when her dentist had remarked how quickly the blood coagulated, and she had had no bleeding at all! I found also that her doctor had been giving her a calcium salt for some time before the operation. A blood examination revealed nothing abnormal.

My own opinion is that no patient should be allowed *to leave the operating table until haemorrhage from the* tonsil beds has ceased, whether this has been brought about by the application of gauze or cotton-wool, by an artery forceps, or by a ligature. In spite of the case detailed above I shall continue to ligate a vessel which does not stop bleeding when a cotton-wool swab has been packed in

for a minute or two. I learned to remove tonsils with a guillotine, but I do not think that anyone who has subsequently learned to dissect tonsils after a manner more or less resembling that of Mr. G. E. Waugh and Mr. Tilley would care to go back to the crudities of the guillotine. (The words "propulsion" and "avulsion" so cheerfully used by my friend Mr. Horgan simply make me shudder.) Besides, in the past year I have had regretfully to find septic pieces of tonsils present in two patients who within eighteen months had paid quite large fees to distinguished colleagues of mine to "remove" their tonsils with a guillotine—one of the patients had also had her uvula removed unintentionally. Everyone knows that in a clinic small pieces of tonsil may be left behind when twenty cases or so are being hurried through in an hour or two; but these two cases were private patients and the operators laryngologists of standing whose skill I know and respect, but whose preference for the guillotine I do not understand. The only disadvantage of tonsil dissection is that the surgeon is in the hands of the anaesthetist, who must be experienced in this class of operation.

Since this lengthy correspondence began on the subject of anaesthesia in tonsillectomy, may I say that in some sixteen years' experience I have had one death on the operating table during tonsillectomy, and in that case the anaesthetic was ether and the anaesthetist sufficiently experienced—the anaesthetic registrar at a teaching hospital; death was not due to haemorrhage, but apparently to shock; the *post-mortem* report called it "status lymphaticus."—I am, etc.,

London, W.1, Jan. 25th. R. SCOTT STEVENSON.

SIR,—The correspondence in the *Journal* upon the subject of haemorrhage after tonsil operations is of great interest, if only for the enormous divergence of the opinions expressed. Most of the letters are from surgeons who practise diverse methods and are prepared to draw the pen and defend their own particular procedure to the last drop of ink. Perhaps the experience of a general practitioner who has seen many of the throat surgeons in London at work may be of some interest.

Since the war I have had 221 cases of tonsillectomy in my practice performed by fourteen different surgeons, no two of whom have operated in exactly the same way. There have been only four cases of severe post-operative haemorrhage and eight cases of haemorrhage of a minor nature. In three of the four serious cases the guillotine has been the instrument of removal; the fourth was after dissection by forceps and curved scissors. I have never seen any trouble from ligatures, and fail to understand why bleeding points in the throat should not be arrested in the same common-sense way as in any other part of the body. Indeed, I remember vividly one patient whose throat at the end of the operation was festooned with ends of catgut, but neither undue soreness nor undue subsequent fibrosis occurred.

In children, particularly, it seems to me that too little attention is paid to the coagulation time of the blood, which my experience leads me to believe has wide variations. If my own children had to undergo this operation I would insist on the point being investigated, and, if necessary, the adoption of appropriate treatment prior to surgery.

In conclusion, I feel sure that, as in most other medical and surgical matters, there is no routine method of tonsillectomy that is applicable to all cases, *pace* the enthusiasts, but that each case needs consideration as to the best method of attack.—I am, etc.,

London, S.W.1, Feb. 4th. DESMOND MACMANUS.

SIR,—I have read with much pleasure the correspondence on tonsil operations. It happens that an exceptionally large proportion of my own tonsil cases are adults, since I live in an area where school medical inspection has not been at work, and so the cases are not "caught young," so to speak. I think dissection the operation of choice in adults, for (*a*) a skilled dissector will make a clean sweep in all cases, and (*b*) the guillotine fails frequently unless anaesthesia is pushed to an anxious degree. In my experience haemorrhage may be equally profuse with either method. I think we cannot exaggerate the importance of preventing haemorrhage. Even cases with a comparatively "mild" haemorrhage at operation may suffer from its weakening effects weeks later. Some time ago I saw two cases of lung abscess, one following a nose and the other a tonsil operation. I am inclined to attribute both to not sufficient attention to bleeding during the operations. Incidentally, I would like to ask if this lung complication can really be as rare as the literature, excepting American, suggests. Finally, I feel I can never attain the speed of several writers who apparently dissect in the time allowed by a dose of ethyl chloride—forty to sixty seconds. I think chloroform and ether, about equal parts, ideal, but to be happy in all cases I follow the stages of anaesthesia during operation.—I am, etc.,

Galway, Feb. 5th. CONOR O'MALLEY.

*** This correspondence is now closed.

PYORRHOEA ALVEOLARIS.

SIR,—In your leading article on pyorrhoea (January 19th, p. 115) you say, "Mucus may stagnate, but hardly normal saliva, which, from whatever source, is always fluid." But surely it is the normality of the saliva and not its fluidity which prevents any deposit? Have we not an analogy in the double solution and deposition of calcium in the form of stalactites and stalagmites, the solution depending on weak carbonic acid, so liable to change.

The condition of the saliva readily alters in health and disease, especially in digestive diseases; and in acute diseases mucin and lime salts quickly deposit round the teeth margins. The normal saliva is said to be mildly alkaline; but ordinary salivas seem to have a wide range of reactions. In some patients the reaction is alkaline, in others it is acid or even amphoteric. The tongue and saliva are responsible for the cleanliness of the mouth and will prevent deposits under normal conditions in healthy subjects. In addition, there is Nature's remedy for dental troubles—tooth and gum suction, which is sternly checked in early childhood; but even yet with some people the tongue is most sensitive to the needs of the mouth.

In discussing treatment Mr. Humphreys suggests saline massage, and says "the salt promotes a flow of serum into the pockets"; but it does more than this, as may be tested by dropping 10 to 30 grains of salt on the tongue and insalivating this for a minute before ejecting. There is an immediate increase of saliva, of mucin as well as of fluids, the mucin to counteract the effects of the irritant. Saliva flows freely for some considerable time afterwards and the reactions are modified, varying, of course, with the type of "common" salt used. Dentists have recommended a strong solution of salt as a dentifrice, and old-fashioned "strong salt solution" still holds its place as a throat and mouth wash.—I am, etc.,

Middlesbrough, Jan. 25th. J. M. MACPHAIL.

DENTAL SEPSIS.

SIR,—In your issue of February 2nd (p. 221) Dr. Bailsford states that I have misrepresented Mr. Humphreys's and Dr. Weston Price's views on the value of the radiogram. I do not agree. Mr. Humphreys's statement, "I believe radiographic evidence, taken alone, to be wholly inadequate and often misleading," proves to me that he does not consider *x* rays infallible. Dr. Weston Price states that more than 10 per cent. of septic teeth show no radiographical evidence of disease. That is enough for me; I am not in a position to challenge such an authority. One has only to take the case of a granuloma in line with the root and not projecting below it, to realize the shortcoming of *x* rays for (at least) certain teeth. The granuloma so often found is a protective mechanism; if the virulence of the organisms is such that no granuloma forms there will be no radiographic signs. I have had such a case—a gold-crowned tooth, which showed no *x*-ray or clinical signs of disease, but which, when extracted, revealed a pulp chamber full of pus and a granuloma.

It was removed on account of a slight peculiar pain which developed during an attack of lymphangitis. This pain, which may be felt for perhaps a day or two, is very characteristic and easily recognized by anyone who has had previous experience of it.

I sincerely hope that in his last paragraph Dr. Brailsford did not infer that I am an advocate of wholesale extractions. I hold that many of the cases which were cured by such would have had the same good outcome with removal of a few teeth or possibly a single tooth. He concludes with a surprising inference about root-filled teeth. If the pulp was alive at the time of exposure and was treated aseptically there is little danger, comparatively speaking. Surely, however, a dead tooth which has had no root filling is a far more serious problem than one which has had this treatment, as the majority of the space is filled with gutta-percha, though this undergoes a 15 per cent. shrinkage (Weston Price). To quote from an excellent but badly titled article by Dr. A. C. Gould,[1] Ulrich finds that 83 per cent. of 1,350 cases of dead teeth in ill patients showed evidence of rarefaction, whereas 68 per cent. of those treated by root fillings revealed that change. Black's figures are even more striking; only 9 per cent. of those with good root fillings demonstrated evidence of disease, while 63 per cent. of those with poor ones showed it. In this connexion we must remember that Mr. Sprawson holds that the drugs employed in the root treatment may themselves be responsible for rarefaction.—I am, etc.,

London, W.1, Feb. 2nd. A. P. BERTWISTLE, F.R.C.S.Ed.

DEBILITY IN CHILDREN AND CYCLICAL VOMITING.

SIR,—In the *Journal* of January 26th (p. 150) there appears an interesting and important article on the above subject by Dr. Osman, in which he describes the biochemical findings in the large class of debilitated children attending hospital, and states that they show similar findings—perhaps to a less degree—to the cases of cyclical vomiting supposed to occur chiefly in the offspring of the more highly educated and well-off people with nervous instability—namely, acetonuria—and that these debilitated hospital patients keep free of all the ailments enumerated in the article by the simple means of increasing their sugar intake.

Although Dr. Osman confines his remarks to children, I can, as a result of work along these lines for several years, confirm his findings as regards the important part played by disturbed hepatic chemistry (of which acetonuria is often a frequent finding) in the debility of adults as well. In fact, my conclusions are that this metabolic aspect of disordered health, as a predisposing cause to diseases of varying kinds (including those of epidemic type), is an extremely important one, and probably is the key to the solution and prevention of many such diseases.

But I cannot confirm the satisfactory results which Dr. Osman gets by his giving simply a more liberal ration of sugar. One would think that a glut of sugar, sweets, and carbohydrates would be more likely to be present in such cases. Although the giving of alkalis and glucose is the routine adopted in all such cases, instances occur in children and adults where sweet things are greatly disliked and absolutely refused. One would hardly expect such complete aversion to something which the body economy urgently needs.

Again, although the suggestion made that in those cases there may be an overaction of the adrenals—turning out the glycogen store of the liver would fit in with the need for more sugar—yet this hardly seems to fit in with another aspect of such cases, where a young child belonging to the type of family with a history of the migraine-eczema-cyclical vomiting type gets severe asthma attacks following on the attacks of liver upset with acetonuria. An increased adrenaline content in the blood should prevent such an occurrence.

Dr. Osman mentions the subject of transient strabismus in debilitated children, it is often more lasting, and, according to the mothers, it seems to vary with the state of health of the child. May it not even be a factor in inducing strabismus in children of pre-school age? It certainly is not confined to children, as I have seen several cases in adults, where the sudden onset of diplopia, often accompanied by sickness, may be very misleading, unless one is on the look out for such causes. I saw last week a woman, aged 65, who suddenly developed a complete paresis of the internal rectus of one eye with resulting embarrassing diplopia due to this cause; it lasted two to three days.

With regard to acetonuria and its treatment by sugar, Green's *Encyclopaedia of Medicine*, after recording the various conditions in which it can be found, which include toxic gastro-intestinal disorders, starvation, and indigestion, especially in children, continues:

"Its occurrence in these cases has been ascribed to organismal toxaemia, and auto-intoxication—but the view held by most of those who have paid particular attention to the subject is that in these, as in other cases, defect in the oxidation of carbohydrate is to blame."

Since this seems correct one cannot see that the administration of more sugar alone is the correct treatment of such cases.

A point not mentioned, but which I am certain has an important relation to the onset of attacks of this type of disorder, is changes in atmospheric conditions. At certain times of the year, among one's patients where such troubles tend to recur periodically, if a few show relapses, then one can count on hearing of all the others having relapses also, sometimes almost on the same day. The effect on health of changing meteorological conditions is not confined to this class of case, but is noticeable in many other patients who do not habitually exhibit this type of constitution, but whose systems show similar changes, when so acted on, to those of the cyclical vomiting child. This is what occurs in so many people who get run down, especially prior to epidemics of colds and influenza. I find confirmation of this view of susceptibility to infection in the *Epitome* of January 26th (para. 82), in which it is stated the epidemics occur because the soil is prepared by altered meteorological changes and not perhaps so much because of the increased virulence of organisms. Some seasons appear to be more severe than others in acting adversely on people's health; the last six months have been particularly so, as evidenced by the large number of obscure cases, of which the one common finding was an acetonuria, and this in spite of a glorious summer.

Dr. Osman's reference to the view held by Professor Vining of Leeds as to the pre-rheumatic child being a case of toxic debility, and his suggestion that all that is required to restore such children to health and prevent the onset of acute rheumatism is a more liberal supply of sugar, calls for some comment. That the urinary findings resemble some of Dr. Osman's findings I agree, but that the well-balanced diet suggested by Professor Vining converts itself into just an extra supply of sugar I do not believe. In what way would this liberal supply of sugar clear up the unhealthy offensive stools of those toxic, debilitated children? The acidophilic group of bowel organisms do not so easily get the preponderance over the proteolytic group by simply giving more sugar. When Professor Vining suggested this view some years ago I gave it my hearty support, since it was the first time I had heard any authoritative statement of a view I had come to hold for some years previously.

That the problem is as easy of solution as Dr. Osman states I cannot believe. The subject is one requiring much more detailed biochemical investigation than the finding of acetone bodies in the urine. No reference is made to other chemical findings in the urine of these cases, nor to the findings (microscopical) in a centrifuged deposit. I think the interpretation of the bodies found in this class of case by the microscope would give important clues as to the links in the chain of the disturbed metabolism. The problem, as it appears to me, is one which not only has reference to the intestinal hepatic chemistry, but reaches out to the *p*H of the blood and the calcium content thereof; it also includes the thyroid-parathyroid mechanism

[1] Symptomless Root Canal Filled Teeth. *Journ. Amer. Med. Assoc.*, 1928, i, p. 1552.

of body defence, and its effect on regulating the acid-base content of the blood. It is interesting in this connexion to recall a statement made, I think, by Llewellyn Jones, that many rheumatic cases are subthyroidics.—I am, etc.,

Darlington, Jan. 26th. R. CHALMERS, M.D., F.R.C.S.Ed.

SIR,—In his article published on January 26th (p. 150) Dr. Osman does not explain why acidosis is present in the cyclical vomiting associated with debility in children, otherwise he would have told us how it is that the administration of sugar alleviates the symptoms.

He states that cyclical vomiting is due to depletion of the glycogen reserves of the liver; this cannot cause acidosis. No doubt the glycogen reserves are depleted, and for a very good reason; it is not the cause, however, but is only a phenomenon resulting from imperfect metabolism. It is the acidosis which is responsible for the symptoms, and this, in turn, is due to the imperfect combustion of fats. One has only to remember that the complete combustion of fats cannot occur without the presence of sugar, and the solution is obvious. So many grams of sugar are necessary to burn so many grams of fat, so that when sugar is scanty or fat over-abundant the fats are imperfectly broken down and acidosis is brought about.

I notice in the same issue of the *Journal* (p. 165) an annotation on the dangers of cod-liver oil; after mention of the deaths of two children who were given the oil the question is asked: "Is it possible . . . that contributing to the toxic symptoms was a ketosis produced by excessive fat feeding?" I do not think there is any doubt about it at all. Dr. Osman rightly states that the child subject to cyclical vomiting is especially liable to delayed chloroform poisoning. This is doubtless so, seeing that chloroform is a fat solvent and the blood and tissues are flooded with fat. Glucose, again, should be given here, and would rapidly restore the normal metabolism of the two substances—indeed, it should always be administered before anaesthesia with chloroform or ether.

In an article on "Glycosuria and cancer" appearing in the February issue of the *Practitioner* I have gone more fully into this subject.—I am, etc.,

Upholland, nr. Wigan, Jan. 31st. J. THOMSON SHIRLAW.

AMAUROTIC FAMILY IDIOCY.

SIR,—I must thank Dr. Robert Platt for his replies (January 26th, p. 177) to my queries upon the pedigree of amaurotic family idiocy (January 19th, p. 101). Unfortunately the only known marriage between relatives is that shown in the table—the great-grandparents of the latest case. Any relationship between Rebecca and her husband, if it exists, must have been more than four generations back at the very least, and probably many more, and the same applies to her father and mother. The families concerned came from widely separated places in Eastern Europe, a thousand miles or more apart, at a time when travel facilities and inclination were almost non-existent, particularly in Russia.

If there were originally an equal number of DD and DR types the probable DR's in the next generation are in the proportion of six to nine DD's, and in succeeding generations this figure becomes further reduced both by geometrical progression and by the greater chance of marriage between DD's. The disease, then, should be of declining incidence, and at one time have been so prevalent as to characterize a scourge to a race instructed to multiply exceedingly; it would be surprising if it were so and yet had passed unnoticed until 1881.

It is naturally a delicate matter to probe into the past history of mental deficiency in any family, especially one indirectly concerned, such as that of Jacob's wife (from whom the nature of the trouble is at present being withheld), but I believe that such negative facts as I have been able to elucidate are true in substance; a medical man of their own race might be in a more favourable position to obtain fuller family histories.

It is difficult to dogmatize on a single case, but I think in so rare a disease it establishes its hereditary nature, even if it does not seem easy to reconcile it with the Mendelian law as at present accepted.—I am, etc.,

Hull, Jan. 28th. D. D. STENHOUSE STEWART.

LIPIODOL.

SIR,—We quite agree with Dr. James Adam (February 2nd, p. 225) that the oral route for administering lipiodol is an excellent one. In our book we describe it as the simplest and, in some cases, the most pleasant method, and the method of choice in many cases. The technique that we describe is simpler than that favoured by Dr. Adam. It is far from easy, however, in very young children, and therefore we advocate, with Dr. Leonard Findlay, who has had a large experience with children, the employment, of brief general anaesthesia. We cannot but feel that to hold the child down in any way must be harmful psychologically to the child.—We are, etc.,

F. G. CHANDLER,
W. BURTON WOOD.

London, Feb. 2nd.

ASTHMA.

SIR,—If Sir James Dundas-Grant will honour me by referring to my book published in 1923 he will see that I am fully conversant with the work of Brodie and Dixon and the nasal reflex as a cause of spasm of the bronchial muscle.

A variety of operative procedures on the nose and its accessory sinuses have led to the cure of individual cases of asthma; sometimes the benefit received has been out of all proportion to the triviality of the surgical interference—a touch with the cautery, or the removal of some insignificant spur. On the other hand, there is a type of asthma in which gross lesions in the nose are almost invariably found, and in which the prognosis is as bad as it can possibly be. I refer to the "aspirin sensitive type." No one who sees large numbers of asthmatics can fail to recognize this type sooner or later. Dr. Francis called attention to it some years ago. Apart from many other symptoms which go to make up this clearly defined type of asthma, patients sensitive to aspirin almost invariably suffer from nasal polypi. Can Sir James help us by suggesting why this should be so? Have the rhinologists any theories as to how polypi are formed, because, if they have, the information may give some clue to the cause of the dreadful attacks of asthma from which these people suffer.

We have, then, a great variety of proceedings which may cure asthma and, to mention a few more, I have known relief follow the removal of an appendix, the excision of an infected gall-bladder, and the enucleation of unhealthy tonsils, which brings us back to the starting-point that "there is not any one form of treatment which is effective in all cases of asthma," and to which we may well add "there never will be." In answer to Surgeon Rear-Admiral Jean's letter, I may say that I am not quibbling with these platitudes, but with the method of the press which has given that gratuitously informed the public that there is a cure for asthma.

One has often wondered why I should appear to be overstating my case, the root and [illegible] your readers to the account of the meeting at coming of x rays [illegible] cause, as recorded in your issue of January loma so often fo[illegible] Arthur F. Hurst, chairman of the virulence of the orga[illegible] committee of the Asthma Research there will be no radio[illegible] one thing he felt sure about was case—a gold-crowned to[illegible] there was still no cure for it." clinical signs of disease, [illegible] Hurst's personal experience revealed a pulp chamber full of

---

(a) a skilled [illegible] and (b) the guillotine fails [illegible] anaesthesia is pushed to an anxious degree.

as an asthmatic, I do not consider his statement correct, nor a fair estimate of the prognosis of asthma as treated by modern methods.—I am, etc.,

London, W.1, Jan. 28th. FRANK COKE.

SIR,—I was pleased to see a letter from Mr. Frank Coke in your issue of January 19th (p. 133). I fail to see why the public should be expected to subscribe to a fund which states in its propaganda that there is no cure for asthma. The most difficult thing to understand is what exactly is meant by "there is not any one form of treatment which is effective in all cases of asthma." Is there any disease, or symptom of disease, to which this is not applicable? As a matter of fact, every case of asthma which is carefully and thoroughly detoxicated will derive appreciable benefit, independently of such other treatment as may be indicated. I have been studying asthma for the past ten years, and since I have had the opportunity of observing Dr. James Adam's work at first hand I approach my cases with far greater confidence of a cure than I would in treating any other chronic condition.

Have the Asthma Research Council sifted the evidence of the men in this country who claim to be able to cure or even satisfactorily treat asthma? If this were done I am sure it would be seen that asthma is as treatable as any other condition, and that cures are being regularly obtained. The reason this work is not generally known is *that only societies* may raise their voices, whilst the individual spends a good deal of his time in avoiding publicity, with loss to humanity as a whole.

I would humbly suggest that we have a *greater knowledge* of this subject in this country than anywhere on the Continent, or, for that matter, in the world, with the possible exception of America, and that if this knowledge is used and developed and encouraged the conquest of asthma is immediately at hand.—I am, etc.,

F. HARRINGTON, M.R.C.S., L.R.C.P.

Newcastle-upon-Tyne, Jan. 23rd.

SIR,—I am *glad that* Sir James Dundas-Grant has drawn attention to the good results of nasal treatment in relieving asthma. The matter requires emphasis. In those asthmatics who have a deflection of the nasal septum, especially an *upper deflection, submucous* resection of the whole or of the upper part should certainly be undertaken if a reasonable trial of other forms of treatment has failed. The result of the operation is often surprisingly satisfactory. Two recent cases are illustrative. They were both middle-aged, rather frail women, for whom many treatments had been tried without avail. One had *developed into* a constant invalid, the other into a periodic one. The removal of the septum has practically cured the asthma and changed the patients into comparatively strong, active women.—I am, etc.,

Bath, Jan. 27th. H. NORMAN BARNETT.

AN APPEAL BOARD FOR SCIENCE.

SIR,—The most important reform needed in science is the formation of an appeal board to establish facts, particularly those of great importance to the *nation*. It is very doubtful whether anyone would be able to establish the fact of the circulation of the blood at the present time had this not been already done, or whether any young *man* discovering a fact that would lead to the cure of cancer would obtain any recognition in his lifetime. Few are likely to be as fortunate with their discoveries as I was with mine. Having discovered shortly after I was qualified that 50 per cent. of the dangerously colour-blind could get through the wool test, and that *about 50 per cent.* of those rejected by it are practically normal sighted, it only took *me twenty-five years'* persistent effort, with the help of the *British Medical Journal*, and against the strongest opposition of the Royal Society and Cambridge, to establish the fact that one colour-blind *person could* pass the wool test, a fact which could have been proved in a quarter of an hour.—I am, etc.,

London, N.W.2, Jan. 21rd. F. W. EDRIDGE-GREEN.

PROPHYLAXIS AND TREATMENT OF DIPHTHERIA.

A Correction.

SIR,—Professor S. Korshun of the Elias Metchnikov Institute for Infectious Diseases of Moscow has drawn my attention to an error in my paper on this subject in the *Journal* of August 25th, 1928 (p. 337). The Russian town where fatalities were caused through the administration of diphtheria toxin in mistake for anatoxin was not Moscow, as stated by me, but Tashkent. At Moscow, Professor Korshun informs me, more than 25,000 children have been immunized by a neutral toxin-antitoxin prepared according to his method, without any fatalities.—I am, etc.,

London, S.W.6, Feb. 4th. J. D. ROLLESTON.

Obituary.

F. DE HAVILLAND HALL, M.D., F.R.C.P.,

Consulting Physician to the Westminster Hospital.

As announced briefly in our last issue Dr. Francis de Havilland Hall died at his home at Twickenham on January 27th. He was born on April 10th, 1847, the fifth son of William Hall, a successful general practitioner at Tottenham. In childhood he was familiar with the life of a family doctor of the old school, and came into daily touch with the routine of surgery and dispensary, the day-book and the ledger, thus gaining a valuable foundation for the work of a busy hospital physician and consultant. From those early days sprang his practical sympathy with members of the medical *profession, and in after life his* help and advice were constantly sought by colleagues on personal matters of health.

De Havilland Hall entered as a student at St. Bartholomew's Hospital in 1866, where he was clinical clerk to Dr. Farre and Dr. Patrick Black, and dresser to Sir James Paget, his house-surgeon being H. T. Butlin, afterwards Sir Henry Butlin, President of the Royal College of Surgeons and of the British Medical Association. Having obtained the M.R.C.S.Eng. and L.S.A. diplomas in 1868 Hall graduated M.B.Lond., and while house-physician at St. Bartholomew's passed his final M.D. examination in 1872. Two Bart's physicians who deeply impressed themselves upon him were James Andrew and Samuel Gee. In 1875 he was appointed medical registrar to the Westminster Hospital, and began his lifelong attachment to that institution, which he served in succession as assistant physician, physician, consulting physician, vice-president, and member of the house committee. He became a member of the Royal College of Physicians of London in 1875, was elected a Fellow in 1881, acted as examiner in medicine for two periods, was a member of the council from 1901 to 1905, censor in 1908–10, and Lumleian Lecturer in 1913, choosing as his subject "Intrathoracic aneurysm." In 1903–4 he held office as president of the Medical Society of London.

Dr. de Havilland Hall married in 1879 a niece of Sir Thomas Smith, at that time surgeon to St. Bartholomew's, and for the next forty years his home was at 47, Wimpole Street. He is survived by his widow, one son, and three daughters. Both sons served with distinction in the war, and the younger died of wounds received at Salonica.

We are indebted to Mr. WALTER G. SPENCER, consulting surgeon to the Westminster Hospital, for the following appreciation:

De Havilland Hall, after holding residential posts at St. Bartholomew's Hospital, gained an insight into private practice. Appointed medical registrar and tutor at Westminster Hospital, then elected to the staff, he was for nearly twenty years physician to out-patients; in consequence he was led to adopt what became characteristic of his teaching, precise detail as to medical treatment and prescribing, categorical instruction in the manner an examinee must answer questions, and various modifications of hospital practice necessary in private practice. Later, when as full physician he held clinics in the wards, his special experience enabled him, in a manner rarely attained by his junior colleagues in tutorial classes, to consider the needs of students about to embark in general practice.

De Havilland Hall, in a number of publications, proved himself a clinical observer of the first class. He had, in addition, two sidelines—laryngology and life insurance. Until he became full physician he conducted the laryngological department, and with his close friends Butlin and Felix Semon was among the founders of the Laryngological Society. He wrote a popular textbook on *Diseases of the Nose and Throat*, and when a new edition was called for Mr. Herbert Tilley joined him and added much on surgery. As medical officer to the Law Union and Rock Insurance Companies, he continued work after his retirement from Wimpole Street. The loss of de Havilland Hall from the consulting staff of Westminster Hospital, following upon that of Mr. William Wroughton from its house committee, removes the last of the personnel as it existed forty-two years ago. Hall kept up a continuous intimacy with many members of the St. Bartholomew's staff, and I owed much to him for the introduction he gave me on my appointment. Throughout our time together we corresponded, physician with surgeon: Hall was quick in coming to a diagnosis as to whether a case would be benefited by medical treatment. Alternatively he was on very many occasions prompt in giving me opportunity for a surgical operation early. His optimistic temperament was subjected of late years to many trials. Chronic diabetes had to be held in check and abstemiousness, for which he had always had a personal inclination, as regards food as well as drink, was increased. The sudden death of his great friend Frederick Palmer cut off the companion of his weekly walks, and finally he had to suffer much from malum coxae senile. When last we met in the board room about a month ago, he, with two sticks, hardly able to hobble one hundred yards, was just his cheery self, full of reminiscences, and hopeful that the worst of the pains had passed off.

"C. B. G.," a friend of fifty years' standing, writes:

Dr. Hall had a signally gracious and happy style and manner, so transparently sincere, high-minded, and true that friends and patients alike trusted him through and through, and as a result he was rightly rewarded with a fine consulting practice of high order, which his painstaking and always up-to-date scientific knowledge amply merited. Although saturated with the love of his profession, Dr. Hall, like all wise men, had many and great interests outside it. His reading was wide and extensive: all historical and biographical and much theological matter was keenly read, English literature of a hundred or so years ago especially appealing to him. He was a devoted "Johnsonian," and a life member of the Lichfield Society, keen also on the Huguenots Society, which he joined in 1904 and whose meetings he delighted to attend. He was a capital talker, with a large range of general information, and also a good listener and a most acceptable and congenial companion. Epsom College owes him much, and so does the Society for Relief of Widows and Orphans of Medical Men, also the Medical Sickness, Annuity, and Life Assurance Society, of which he was chairman from 1893 to 1911 and president from 1912 to 1920, when the society was changed into a mutual company.

The funeral service, which took place at Holy Trinity Church, Twickenham, on January 30th, was attended by many of Dr. de Havilland Hall's old friends in the profession, as was also a memorial service held on the same day at All Saints' Chapel, Westminster Hospital. The interment was at Teddington Cemetery.

THOMAS DUNCAN GREENLEES, M.D.

Formerly Medical Superintendent, Grahamstown Asylum.

WE regret to announce the death of Dr. T. D. Greenlees, which occurred at his home at St. Leonards-on-Sea on January 22nd. He was among the best-known members of the medical profession in the Hastings district in recent years, and had attained a prominent place in the British Medical Association, having served as a member of the Central Council with only two intervals—each of a year—from 1903 to 1925. In earlier days he was a leading figure in the affairs of the Association in South Africa.

Thomas Duncan Greenlees received his medical education at the Universities of Glasgow and Edinburgh, graduating M.B., C.M.Ed. in 1882, and proceeding M.D. in 1901. He devoted himself largely to psychological medicine, and spent the greater part of his career in work in various mental institutions. He was at one time assistant medical officer at the City of London Asylum at Stone, and afterwards went to South Africa as medical superintendent of the Grahamstown Asylum, in which position he spent a number of years. Later he became resident physician and superintendent of the Fenstanton Asylum at Streatham Hill, and subsequently, six or seven years ago, he went to live at St. Leonards-on-Sea. He was the author of a number of contributions to current literature on questions relating to insanity, and in 1885 was a prizeman of the Medico-Psychological Association. He was also a Fellow of the Royal Society of Edinburgh.

The record of Dr. Greenlees's services to the British Medical Association extends from 1927 back to 1893, when he became, during his stay in South Africa, honorary secretary of the then Grahamstown and Eastern Provinces Branch, in which he later held office successively as honorary treasurer and as a member of the Branch Council for several periods. His connexion with the Central Council began in 1903, when he was elected as representative of the Cape of Good Hope Eastern, Western, and Border Branches, remaining a member until 1918. He again served on the Council in the year 1919-20 and from 1921 to 1925, and during this latter period was particularly associated with the work of the Dominions Committee. At the Annual Meeting of the Association in London in 1910 he was vice-president of the Section of Psychological Medicine and Neurology. Dr. Greenlees had been also chairman of the Norwood Division in 1910-11, and deputy representative in the Representative Body of the Hastings Division in 1927, and had served upon the executive committees of both these units.

Outside his professional affairs he was a member of the Freemasons' organization and a faithful adherent of the Baptist Church, in which he was a deacon. He leaves a widow, a son, and two daughters. A colleague writes: The Hastings Division of the British Medical Association has sustained a severe loss by the sudden death of Duncan Greenlees. He had been in indifferent health for a long time, and his Divisional activities had as a consequence been much curtailed. His zeal for the Association was such that he would often attend meetings when, as everyone knew, he should have been conserving his strength to fight his old enemy, asthma. This serves to illustrate his character. His love for his profession, his brethren, and the Association was very keen. His colleagues will sadly miss his kindly advice and his ready wit.

JOHN OWEN, M.D., F.R.C.P.

Physician, Liverpool Royal Infirmary; Lecturer in Clinical Medicine, University of Liverpool.

WE have to announce with much regret the death, on January 23rd, from acute pneumonia, at the age of 55, of Dr. John Owen, one of the leading figures in medicine in Liverpool, where he held many important offices.

John Owen received his early education at Beaumaris Grammar School, from which he passed to University College, Bangor, proceeding thence to study medicine at University College, Liverpool, and, later, at Guy's Hospital. In 1897 he obtained the diploma L.S.A., and graduated M.B.Lond., proceeding M.D. in 1906, having, a few years before, obtained the D.P.H.Camb. In 1903 he became a Member of the Royal College of Physicians of London, and in 1923 he was elected a Fellow. After first qualifying he held a resident appointment at the Royal Southern Hospital, Liverpool, and then practised for a year or two in partnership at Blaenau-Festiniog. During the South African war of 1899–1902 he served as a civil surgeon to the South African Field Force, and at the conclusion of hostilities returned to London. While acting as casualty officer to the St. Pancras Dispensary he continued his studies at Guy's Hospital, and then began practice as a physician in Liverpool, where his ability was soon recognized. At the time of his death he was honorary phy-

to the Liverpool Royal Infirmary, and lecturer in clinical medicine at the University of Liverpool. He was also honorary consulting physician to the Home for Epileptics, Maghull, the Liverpool Eye and Ear Hospital, the Liverpool Dispensary, the School for the Blind, and the Southport Infirmary. At an earlier period he had been honorary physician to the Liverpool Hospital for Consumption, the Liverpool Northern Hospital, and the Stanley Hospital. He held a commission in the R.A.M.C.(T.F.) for many years, and during the war of 1914–18 served in India and Mesopotamia, retiring with the rank of major and the Territorial Decoration.

Dr. Owen's interest in professional matters was concerned mainly with the scientific side of medicine. His contributions to its literature, in the form of articles written for various periodicals, were largely on neurological subjects. He was a member of the Association of Physicians of Great Britain, and of the Liverpool Medical Institute. At the Annual Meeting of the British Medical Association at Liverpool in 1912 he was honorary secretary of the Section of Medicine. Dr. Owen was unmarried, but is survived by his mother, to whom he was devoted, and for whom deep sympathy is felt by a large circle of friends in Liverpool and elsewhere.

Sir JAMES BARR writes from Cannes:

The death of Dr. John Owen must cast a gloom over the medical profession in Liverpool, since he was universally beloved both by his professional brethren and the public. To me his death came as a great shock, as it is only about two weeks since I had a long letter from him on a subject in which we were mutually interested, and he then gave no indication of any impairment in his usual good health and vigour. John Owen, although very unassuming, knew his work well, and was extremely careful both in diagnosis and treatment. He was a man who inspired confidence—a confidence which was never misplaced. He was thoroughly imbued with the best traditions of the medical profession, and was ever ready to lend a helping hand to those in distress without any ulterior motives. His charitable deeds in the profession and outside will keep his memory green in many a household. On my return to Liverpool I shall sadly miss another old and valued friend.

Colonel A. W. SHEEN writes from Cardiff:

I am minded to write a tribute of warm affection and regard, shared, I know, by all his war comrades, to the life and memory of John Owen. When I commanded the Welsh Hospital in India, of 3,000 beds, "Major John," as we all knew him, was in charge of the Medical Division. His good work, his kindness, and his personal charm endeared him to all. And there were in his character special traits of modesty, humour, and fearlessness. The last was shown by his zeal for "tiger," and by some feeling of sorrow in him that his lot had not been cast in a more active theatre of war. But duty was paramount with him: our change of destination from France to India he accepted with willing cheerfulness, and although, later, the charge of a hospital ship brought him in contact with Mesopotamia, yet the field of battle did not come his way. I only knew of his death from a notice in the *Times* on the day of his funeral, a death which I feel must have been contributed to by devotion to his work, in which he never spared or thought of himself. His loss will be felt by all the many with and for whom he lived and worked in Liverpool, and not least by those who knew his sterling worth and character by friendship and comradeship in the days of war.

C. HUBERT ROBERTS, M.D., F.R.C.P., F.R.C.S.,

Consulting Surgeon to Queen Charlotte's Maternity Hospital and the Samaritan Hospital, London.

WE regret to announce the death of Dr. C. Hubert Roberts, which took place suddenly at sea near Denmark on January 29th, in his sixty-fourth year.

Hubert Roberts, after leaving Bedford School, studied medicine at St. Bartholomew's Hospital, where he was a brilliant student. He gained the junior and senior scholarships in 1885 and 1886, and ultimately won the gold medal in the M.D. of the London University. Soon after qualification he decided to specialize in obstetrics and gynaecology, but was disappointed that his own hospital offered no prospect of a vacancy on the visiting staff. But he was appointed to Queen Charlotte's Hospital and the Samaritan Hospital for Women, where he continued an active member of the honorary staffs until his retirement under the age rule. He was also gynaecologist to the staff of St. Luke's Hostel, and acted as examiner to the English Conjoint Board and other examining bodies.

During the war Roberts, being then well over age for active service, performed useful and arduous work as accoucheur to Lady Howard de Walden's Hospital for officers' wives, and also as a member of the visiting staff of the Epsom War Hospital. He took an active interest in the affairs of the Royal Society of Medicine, and especially the Section of Obstetrics and Gynaecology, of which he was for some time vice-president, after having held the post of secretary and other offices. He was secretary of the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association in Sheffield in 1908. His writings were numerous, and began with a book published in 1901 on gynaecological pathology. Based on his lecture notes, this proved to be a valuable and successful publication.

Roberts's clinical experience was unusually wide, especially in obstetrics. In his earlier years at Queen Charlotte's Hospital he developed a reputation for his manipulative skill in the delivery of difficult cases. There can be very little in the whole range of obstetrics that Roberts had not seen and treated. His views in clinical obstetrics were sound and conservative, and he had no patience with ill-considered opinions and rash methods of treatment. As a gynaecological operator he was not at his best in recent years. While sound in diagnosis his surgical technique was never facile or flexible, and he often gave the impression that operative work was anxious and laborious. But it was as a teacher that Roberts excelled. He enjoyed his weekly round of the wards at Queen Charlotte's probably more than any other part of his work, and there will be many old students and nurses who remember his characteristically jovial style: stories, banter, and reproof all mixed up with the subject of the lecture in a way which compelled attention.

Roberts was a kindly, impulsive man, who made friends freely and who detested a quarrel; indeed, he would go very far to maintain agreement in a threatened dispute. He began life with great promise of a brilliant career, but those who knew him well in later years felt that he suffered a certain amount of disappointment in not having achieved perhaps all he hoped in the ambitious days of his youth.

JOHN ADOLPHUS SHARP, M.R.C.S.,

Consulting Surgeon to the Derbyshire Royal Infirmary, Derby.

WE regret to announce the death of Dr. John A. Sharp, which occurred at his home in Derby on January 26th, in his eighty-second year. He was the doyen of the medical profession in his county, and one of the oldest practising medical men in Great Britain, having continued his regular activities until within two months of his death.

John Adolphus Sharp was born at Maidstone in 1847, and received his medical education at Guy's Hospital, obtaining the diplomas L.R.C.P., M.R.C.S., and L.S.A. in 1868. After holding a resident post at Guy's he became house-surgeon in the old Derbyshire Infirmary, and a few years later set up in practice at Derby. He soon resumed his intimate association with the Infirmary on his appointment as honorary surgeon upon its staff. In this capacity he played an important part in the development of the institution, which was afterwards given the name of the Derbyshire Royal Infirmary. When—some forty years ago—the scheme for its reconstruction was in course of preparation Dr. Sharp made a study of many hospitals on the Continent with the object of ensuring that the plans—in the preparation of which the architects had the benefit of his co-operation—should incorporate the then most recent developments in hospital construction. In 1896 the state of his health compelled him to retire from practice for the

time being, and he went to live in the South of England, taking this enforced leisure as an opportunity to pursue a special course in bacteriology in London. Ten years later, on the death of his successor in practice, he went back to Derby and resumed work there. He renewed his connexion with the Royal Infirmary, in which he was made an honorary consulting surgeon, and until very recently played an active and useful part in its management. He leaves *a widow, one son—a medical practitioner*—and one daughter, whose husband is also a member of this profession.

A colleague writes: Dr. Sharp was not only held in the highest regard by his brother medical men, but also in the greatest esteem and affection by his patients. In spite of his advanced years his activity was extraordinary, and he was an exceptionally sound and painstaking practitioner. Although one of the old school, he nevertheless kept himself well up to date in modern methods of diagnosis and treatment. His striking personality made itself felt by all who were brought into contact with him, and his well-known and venerable figure will be greatly missed in Derby. He was a member of the British Medical Association for over fifty years, and for a period was the local secretary. Great public interest was taken in his funeral, which took place on January 30th, and St. Andrew's Church was filled with sympathizers. Among those present were representatives of the board of management and medical and nursing staffs of the Derbyshire Royal Infirmary, a large number of his professional colleagues, prominent Derby citizens, and city councillors. The Rev. T. S. Jagg, chaplain to the Derbyshire Royal Infirmary, paid a striking tribute to a life which, he said, had been spent in a great work for the town and its people.

VICTOR PLARR, M.A.,

Librarian, Royal College of Surgeons of England.

MR. VICTOR GUSTAVE PLARR, poet, man of letters, student of human foibles, and librarian to the Royal College of Surgeons of England, died on January 28th at his home near Wimbledon, suddenly and unexpectedly, in the sixty-sixth year of his age. He always had the air and stoop of a student, but of late his friends, of whom he had many, both at his College and his club (the Athenaeum), noted that he stooped more, and walked with a slower step, but they took no alarm, for he was a man who smiled on life even when things went awry with him. His Council gave him three months' leave of absence in order that he might regain strength, but in spite of all attention given to him by his medical attendants and devoted wife recovery never came.

The post held by Mr. Plarr was established just over a century ago, and he was the fourth to hold it. His immediate predecessor was Mr. James Blake Bailey, who established a great tradition—the tradition that every visitor to the library was to be welcomed, made comfortable, and helped to the utmost of its resources. On Mr. Bailey's death in 1897 Mr. Plarr, who was then librarian to King's College, Strand, was appointed his successor, and, as the many thousands who have used the library in the past thirty-one years will gladly testify, under him and his able staff of assistants the Bailey tradition has been continued and extended. The card catalogue which was begun by Mr. Bailey was completed; a full list of all the precious manuscripts in possession of the College was compiled and kept up to date. From time to time, with the permission of his Council, he published interesting extracts from the stores at his disposal—letters of the Hunters, of Dr. Matthew Baillie, of the Hunter-Baillie family, letters of Sir Walter Scott, of Joanna Baillie, and of Sir Edward Jenner. He *compiled a complete list of the lectures* which had been given at the College during the nineteenth century, and of the professors and lecturers who had given them. His greatest task was the compilation of a roll of the Fellows of the College; he wrote biographical notices of 2,500 of them. As a biographer it was the personality of a Fellow which appealed to him; the discoveries a man made, the advances which he introduced into his art, were in Victor Plarr's eyes of minor importance compared with the measure of his humanity and the manner in which he dealt with his fellow men. He was a man who looked at life much as Charles Lamb did; the art of "window-dressing" and of "elbowing" was altogether foreign to his nature. He was a spectator who sank himself in his surroundings and watched life go by—sometimes with a wry smile. His measure of a man was not, What has he done? but, How has he lived? Victor Plarr lived to *enjoy life* and to make his companions in life enjoy their share to the full.

Victor Plarr was English to the core, and yet he was born in Alsace under the French flag; his father was a professor in Strasbourg University; his mother, an Englishwoman and poetess, traced her descent from an Aberdeenshire baronet, Sir Alexander Cumming. In 1870, when he was 7 years of age, his parents came to England rather than pass under the German flag. Victor was sent to school, first at St. Andrews and afterwards to Tonbridge, passing to Worcester College, Oxford, in 1882, at the age of 19. He obtained a second class in modern history in 1886, and then sought a livelihood in London. As an undergraduate at Oxford the gift of verse, which he had inherited from his mother, became manifest, and he was received by the young poets of London, who forgathered at the Rhymers' Club, with acclamation. Mr. Morley Roberts knew Victor Plarr then, and has told the writer of the great future which was prophesied for Victor Plarr as a poet—a promise which was never really fulfilled, for *the world judged him finally as a minor poet.* His various books of verse—his *In the Dorian Mood* (1896) and *The Tragedy of Asgard* (1905)—never made their way beyond the narrow circle of professional approval. He was journalist; he edited the fourteenth and fifteenth editions of *Men and Women of the Time*—a publication which was supplanted by the appearance of *Who's Who*. He had not the outfit which is needed to make a success of free-lance journalism. He was pensive and sentimental, and his wares were not such as the public cared to buy. He loved, not the highway of life, but its pleasanter side-paths, where a man may dally and refresh his soul as he passes along. Hence, when the opportunity offered, he gladly sought a career in the shelter of a library, King's College giving him his first post in 1890.

Even when he became a medical librarian, and had charge of one of the finest libraries of its kind in this country, his taste for by-paths still mastered him. To the *British Medical Journal* and to other professional publications he contributed many articles, some signed, most unsigned; but one and all of them deal only with the aspects of medicine which interested him—its folk-lore, its myths, its miracles, its curiosities, and its personalities. In his journalism, as in his verse, he was always an artist; he was self-detached, and looked at things as if they were far off. Like many Oxford men, he covered a sensitive, shy, retiring nature by a pose. In *Who's Who* he has described his *favourite occupations* as "walking," "talking," "sleep," and "pastel drawing." It is true he was an artist with pencil and crayon, and did while away hours of leisure with them; but his real favourite occupation was spent in loyal service to his College and loving devotion to his home.

A. K.

THE LATE DR. WILLIAM T. HAYWARD.

AN obituary notice of Dr. W. T. Hayward, C.M.G., appeared in our issue of January 5th (p. 47). We have since received from a correspondent in North Adelaide ("A. A. L.") the following appreciation:

With the passing of Dr. W. T. Hayward the writer has to lament the loss of a friend and colleague of some forty-five years' standing, and the people of South Australia one who, starting the practice of his profession in their midst just half a century ago, rapidly acquired, and ever maintained, the confidence and esteem of a large circle of patients and friends.

When he had completed with credit four years' course of study at the Liverpool Royal Infirmary, and obtained the necessary certificates, he took a short trip across the Irish Channel in the year 1874, and presented himself before the board of examiners of the Royal College of Physicians. The registrar apparently did not deem it necessary to inquire into age of the student with the long beard, and as a result, still a minor, he became duly licensed to practise, and also

immediately obtained an appointment as surgeon to the Pacific Steam Navigation Company. After a couple of voyages to South America he started work as a hospital intern at Liverpool, becoming M.R.C.S. in 1875. Again he took to the sea, ultimately with the newly formed Orient Company, and he was surgeon of the *Lusitania*, the first vessel of this line to come out to Australia; on board this steamer he met his future wife, the daughter of Mr. F. R. Burden of the *Advertiser* newspaper. In October, 1878, he decided to settle in Australia, and started to practise at Riverton, a country township; in 1882 he removed to Norwood, a suburb of Adelaide, having succeeded to the practice of the late Dr. Baily. Early in his career (1875) he became a member of the British Medical Association, and in 1879 he was instrumental in helping to form in Adelaide the first Branch in Australasia. On the occasion of the accidental death of the then president (Dr. Charles Gosse), in 1885, he was chosen as his successor, and he occupied the chair again in 1910. In 1911, when the various Australian Branches were drawn together by a federal tie, he was chosen as one of the South Australian representatives, and elected the first president of the Federal Committee. Visiting England in that capacity in 1914, he attended the Annual Meeting of the Association at Aberdeen, where he was given the honorary degree of LL.D. of that University, and made a vice-president of the whole Association. His long services to the profession were recognized locally by the presentation to him, in 1920, of his portrait in oils by Mr. Webb; this speaking likeness of him at his best will some day adorn the future Hall of the Association. In 1919 the Gold Medal of the parent Association was presented to him for his distinguished services. In 1885 a vacancy at the Adelaide Hospital allowed of his appointment as honorary physician, and this office he held for many years; he was also an honorary medical officer at the Children's Hospital for a decade. On the retirement of the late Dr. W. L. Cleland he was appointed lecturer in the Medical School on materia medica and therapeutics, resigning this position in 1920. He was for twenty-five years a member of the council of the University, and for a couple of years dean of the faculty. As a clinical teacher he was sound rather than brilliant, and he had the benefit of experience rather than of modern post-graduate teaching. At the Inter-State Congress at Sydney a few years ago he was president of the Section of Medicine.

When the war broke out Dr. Hayward volunteered his services, although over 60 years of age. They were accepted, and he was sent home in August, 1915, to be officer commanding the "nth A.G.H." On arrival in London he was informed that they had never heard of this particular unit, but Sir Neville Howse found him an appropriate billet as the officer in charge of the 1st Australian General Hospital at Harefield. There he spent two years, and was rewarded with the C.M.G. and promotion to full colonel. He returned to Adelaide, but did not resume his suburban practice.

Outside his profession he did not take part in any public work. In private he was charming; a chorister in boyhood, he could play an accompaniment on the piano; as a whist or bridge player he was good, and above all, even-tempered. On a sea voyage as late as four years ago he took an active part in all deck sports; though he never learnt golf he did not disdain a game of bowls. In early life he was a crack rifle shot.

Perhaps Dr. Hayward's greatest professional distinction was the confidence placed in his judgement on all ethical matters; for nearly three decades he was the one always appealed to on these subjects. He was patient, and genial, and understanding; he could recognize the frailties of medical human nature and the allowances to be made for them, but he was the staunch champion of all straightforward dealings. He might perhaps be described as the best type of general practitioner produced by the medical education afforded in the early seventies of last century, a type now well-nigh extinct. While he fully appreciated the distinguished honours that came his way, he wore them with all modesty. He has left a widow and seven children. Three of his sons became doctors: one, Lionel, who died of phthisis in 1926, at the age of 45, earned the remarkable distinction of a hospital at Loxton on the River Murray being named after him in affectionate remembrance.

Dr. SELFE BENNETT, who died, aged 81 years, on January 15th, was the son of Dr. (afterwards Sir) Risdon Bennett of Finsbury Square, physician to St. Thomas's Hospital, and for five years President of the Royal College of Physicians of London. Henry Selfe Bennett went to St. Paul's School, then in its old quarters in St. Paul's Churchyard, and thence proceeded to Trinity Hall, Cambridge. His affection for his old school and college persisted as long as he lived. At St. Paul's he won the English poetry prize, and when the Trinity Hall boat became head of the river he celebrated the occasion in a privately printed poem. He became a student of St. Thomas's Hospital Medical School, M.R.C.S.Eng. in 1874, and M.B.Cantab. in 1875. Curiously enough, he did not obtain the licence of the College over which his father long presided. After holding a house-physicianship at St. Thomas's and a resident post at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, Bennett settled in practice in Seymour Street, subsequently moving to Upper Berkeley Street, where he died. He was for many years medical officer to the London office of the Liverpool and *London and Globe Insurance Company*, until infirmity compelled his retirement on a pension. He was an active member of the Life Assurance Medical Officers' Association, to the *Transactions* of which he contributed in 1908 a paper on the statistical method in medicine, and in 1915 one on influenza. On the first-named subject he held strongly sceptical views, holding that the statistical method was unavoidably fallacious, and he believed that subtle sequelae of influenza were long enduring and often overlooked. He was a collector of prints, chiefly with a view to extra-illustration, which was his chief hobby. His extra-illustrated volumes of *The Gold Headed Cane* were much admired. Bennett was at one time a member of the Organon Club, and for many years a constant attendant at the meetings of the Casual Club, of which he was twice president, and where his facility in debate and his tendency to take up the position of Advocatus Diaboli were much appreciated. In 1917, as the result of an accident, he suffered fracture of the upper part of the shaft of the left femur. Various causes combined to make the result an unsatisfactory one, and the consequent crippling and increasing general weakness confined him to his house, and for the last two years to his bed. He bore all his troubles with stoical resignation and cheerfulness, till bronchitis and progressive congestion, probably affecting the base of the brain, released him quietly and calmly from his troubles. His wife survives him, with a son and a daughter.

Dr. FRANK MORT, whose death occurred on January 22nd at the age of 56, had been resident in Middlesbrough for almost thirty years, and was among the best-known members of the medical profession in the Cleveland district. Born in Glasgow, he received his medical education at the university the[illegible] 1895. Five years later he [illegible] he remained until his death [illegible] writes: Cleveland is poorer for the loss of Dr. Frank Mort. From the time of his coming to the district until his retirement from general practice little more than a year ago he accomplished an astonishing amount of work, though labouring all the time under a heavy burden of ill health. In recent years, notwithstanding the claims of a very large practice, he found time for special attention to cardiac diseases, in which he had always been particularly interested. By constant study, by frequent visits to important cardiological centres at home and on the Continent, by the use of the most modern cardiographic and radiological methods of investigation, he had acquired recognition throughout the Cleveland area as an authority on the subject in which, even after giving up active practice, he maintained unflagging interest. A few days before his death he expressed regret that he would be unable to deliver an address he had promised to a neighbouring Division of the British Medical Association, of which he was a loyal and active member. He took a full share in the work of the Cleveland Division and had served on several occasions on the executive committee, but although repeatedly asked to accept the office of chairman, always refused, saying that there were others better fitted for the post. Such self-effacement and modesty were characteristic of him. Always gentle, always courteous—even when the stress was greatest—always with a kindly smile and a word of comfort, always ready to respond without a murmur to an urgent call, there is little cause to wonder that his people loved him, and that to them he was not simply the doctor, but the trusted friend. As with his patients so it was in his relations with his fellows; they were never his opponents or competitors, but always his professional

brethren. He sought and found the best in everyone and in everything. Never thrusting himself forward, but always ready to help, he earned and kept the respect and esteem of his colleagues and the love of those whose privilege it was to know him intimately.

Dr. WILLIAM GRANT STEWART, who died at his home in Montreal last year at the age of 68, had been in practice in that city for forty years. He was a frequent visitor to Great Britain and had many friends among medical men here. The son of a Presbyterian minister, he received his medical education at McGill University, and after graduating M.D. in 1888 he continued his studies in Berlin, London, and Edinburgh. On his return to Canada he settled in Montreal and soon built up an extensive practice. For many years he was physician to the Western Hospital, and he also took a large part in the medical and managerial work of the Montreal Maternity Hospital and the Alexandra Hospital, among other institutions. Dr. Stewart had been a member of the teaching staff of the University of Bishop's College, where he was for some time lecturer in clinical medicine. In 1919 he was elected president of the Montreal Medico-Chirurgical Society. He was for long an enthusiastic member of the British Medical Association, and prided himself on having been present at the opening of the Association's new House in 1925. During his frequent visits to Great Britain he attended many of the Annual Meetings of the Association, including those at Manchester, Oxford, Belfast, Birmingham, Aberdeen, and Bath. Outside his profession his main interests were in music, literature, and travel. About four years ago his many activities began to tell upon him; cardiac weakness developed, and he was compelled to relinquish the greater part of his work. His death caused deep regret among his many friends and colleagues, by whom he was held in the highest esteem.

We have to record with regret the death, on January 12th, at the age of 84, of Dr. ALICE DRYSDALE VICKERY, at her home in Brighton. Dr. Vickery qualified L.R.C.P.I. in 1880, and was a member of the British Medical Association till 1925. Dr. B. Dunlop writes: Alice Drysdale Vickery, who was among the first five women to obtain a medical qualification in the British Isles, was one of the pioneers of women's progressive movements, and especially of that for birth control. In 1877 she bravely stood as a witness for Charles Bradlaugh and Mrs. Annie Besant in their famous trial for republishing Dr. Knowlton's pamphlet on family limitation. She and her husband, the late Charles R. Drysdale, M.D., then helped to found the Malthusian League, and thereafter largely devoted their lives to writing and speaking gratuitously on the birth rate question. Even when over 70 years of age she continued to attend Eugenics Society and other meetings in London at which she advocated the Neo-Malthusian point of view, and returned home on the top of a bus whatever the season. No history of the birth control movement can be written without a reference to the widely revered name of Alice Vickery, and she will also be remembered by many as a devoted wife, mother, and friend.

The following well-known foreign medical men have recently died: Dr. MAURICE LETULLE, professor of morbid anatomy in the Paris faculty of medicine and member of the Académie de Médecine, aged 75; Dr. LOUIS BROCQ, the eminent dermatologist, consulting physician to the Hôpital St. Louis, and Commander of the Legion of Honour; Dr. CHAPOY, honorary professor of the medical school of Besançon; Professor CARL POSNER, editor of the *Berliner Klinische Wochenschrift* from 1889 to 1921, aged 74; Dr. LUIS BARRAQUER ROVIRATTA, a Barcelona neurologist; Dr. CHRISTOS MALANDRINOS, professor of children's diseases at the University of Athens, aged 55; Dr. EUGENE LATREILLE, professor of morbid anatomy at Montreal University; and Dr. ANDREA AMICI, the Pope's physician, of Grenada.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the College was held on January 31st, when the President, Sir John Rose Bradford, was in the chair.

Membership.

The following candidates were admitted to the Membership:

Edi[illegible] Gerald Vincent Francis Doyle, a, L.R.C.P., Alfred Henry Gerrard, [illegible]nd., land, M.B.*Toronto*, [illegible] pted, M.B.*Camb.*, Sc. [illegible]rson *Nsud*, M.B.*Sydney*, Walter Gordon Chisholm Patterson, [illegible], New Zealand, Robert Sturtevant Pilcher, M.B.Lond., Charles Percy [illegible] M.B.Camb. Francis Cro-bie Roles, L.R.C.P., Cyril Dee [illegible], Clive Henry [illegible]ner, Robert Yorke, M.D. [illegible]ane.

Licences.

Licences were granted to the following 149 candidates, who had passed the necessary examinations of the Conjoint Board and conformed to the by-laws and regulations of the College:

H. H. Aitchison, G. G. Allan, *Lucy E. Arthur, M. W. Atkinson*, S. W. Barber, R. C. Bennett, H. Bornstein, G. H. Bradshaw, *Rochelle Churin*, F. Clifton, G. C. Cochrane, C. E. Corrigan, C. F. *Cosin*, *Florence K. Costello, P. J. Cowin*, D. F. L. Croft, R. Cutler, L. E. Daniel, C. J. M. Dawkins, E. M. Dimock, J. Donovan, H. A. *Eason*, A. M. Easton, J. A. *Eddy*, M. A. A. El Gammal, A. C. *Elkin*, G. W. *Elchos*, T. Evans, T. C. J. *Evans*, A. D. Everett, T. D. Finey, W. R. Forrester-Wood, C. H. Forsyth, E. Foster, R. H. Francis, S. L. Garaye, W. S. Ghai, J. M. Gibson, P. J. C. Godard, M. W. *Gouin*, J. Gordon, J. T. C. Gray, D. R. Griffith, C. C. Griffiths, A. J. Groenewald, *Gwendoline E. Grove, R. G. Gwynne, M. K. Gyi, R. W. Haines, A. S. Hall, R. S. Hamlin, J. M. Harker, H. M. Harris, G. F. Harrison, F. F. Helliker, R. T. *Hicks*, *Louisa S. Hobbs, R. C. Holdernes-, F. W. Holdsworth, G. J. Hollis, A. S. Hoseason, R. I. Hyder, C. G. Johbins, *Margaret L. Jones, O. T. Jones, H. W. [illegible] S. E. Knolwes, L. W. A. Lankester, J. F. V. Lart, *Cesia I. [illegible]ssing, A. Levy, K. Lindberg, A. G. *Lloyd*, R. [illegible] M. Lufkin, R. Machrar, J. K. Marshall, A. M[illegible] R. A. Maynard, E. G. Milad, W. B. Millar, M. V. Modi, G. Morgan, G. H. Morley, J. E. *Myers*, T. H. Negus, D. A. Nicoll, G. S. *Nightingale*, W. G. Oakley, R. I. O'Farrell, T. L. *Owen*, L. G. M. Page, A. J. Paver, A. F. Parker, A. R. D. Pattison, I. Preisbel, B. Pavy, S. M. Rahman, A. S. Rajasingham, T. G. Reah, *Dorothy K. Reynolds, A. C. Riley, G. L. Robinson, V. C. Robinson, T. S. Rodgers, E. B. Rogers, B. Rothery, A. S. D. Russell, H. W. Rycroft, N. Sachnovics, H. R. D. Schofield, T. L. Scott, *Mary Scouloudi, D. A. Seaman, J. E. Semple, G. M. A. *Shaikh*, *Mary E. Sharp, J. D. Simpson, A. D. Skyrme, C. E. Soodeen, A. Southgate, B. Stanley, H. Stark, E. T. W. Starkie, G. A. Stevenson, E. C. Sugden, H. Taylor, I. Taylor, V. C. [illegible] S. A. Underwood, *Bertha O. Upton-Jones, V. C. Verbi, [illegible]nman, C. M. E. Warner, R. P. White [illegible]itrow, A. G. Williams, A. R. Willis [illegible] I. Willmott, G. M. Willoughby, W. R. [illegible] R. G. Zaglama, R. Zimbler.

* Under the Medical Act, 1876.

Diplomas in Special Subjects.

Diplomas in the subjects indicated were *granted jointly* with the Royal College of Surgeons:

D.P.H.—G. M. *Addison*, N. T. Advani, C. L. Ahluwalia, J. S. Allan, A. N. Chopra, Marguerite R. Cliff, W. Conroy, K. St. V. Edwards, Eugene Egan, J. Egan, V. Feldman, J. Ferguson, M. T. Fernando, Barbara Finch, A. N. Ghei, *Winafride M. Gibson*, N. G. Hill, Katherine M. Hirst, D. P. Holmes, *Amelia M. Ison*, C. W. W Jeremiah, Ellen F. Kelleher, W. H. Kelleher, I. D. Khatri, F. T. Lloyd, W. S. Martin, M. V. Merchant, P. L. Nirula, *Mary O'Leary*, Helen E. D. E. *Ornstein*, W. G. Patterson, R. F. Pinson, F. W. G Smith, R. B. Subramanyam, R. W. C. Thambiah, D. J. Valentine, E. M. Wright.

PSYCHOLOGICAL MEDICINE.—R. W. Armstrong, *Eileen A. Channell*, A. Craig, H. Hinchco, Phyllis M. Horton, D. L. McCulloch, D. Menzies, J. E. Nicole, Muriel L. M. Northcote, *Eveleen J. O'Brien*, J. C. Ramsay, C. E. Roachsmith.

LARYNGOLOGY AND OTOLOGY.—M. I. Ashmawi, A. Blagoff, N. M. Ezra, M. Husnain, N. H. Mencio, H. V. O'shea, H. M. Petty, S. Roy, E. C. Tamplin, W. L. Thomas.

Appointments.

Dr. C. H. J. Lockyer was elected Councillor in the place of Sir Hugh K. Anderson (deceased), Dr. Gordon Holmes was elected examiner in psychological medicine, and Dr. W. J. Fenton examiner in medicine.

The award of the Swiney prize for 1929 to Professor Sidney Smith was announced (see *British Medical Journal*, February 2, p. 231).

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—J. S. B. Bray, N. N. Datta, A. R. Edwards, C. F. Hurst.

MEDICINE.—G. E. Bent, J. S. B. Bray, A. Weeks.

FORENSIC MEDICINE.—J. S. B. Bray, *J. Freud*, L. P. Gregory, I. Lloyd-Jones, A. Weeks.

MIDWIFERY.—*J. Freud*, H. G. Edmunds, D. F. Michael.

The diploma of the Society has been granted to Messrs. G. E. Bent, J. S. B. Bray, *J. Freud*, and A. Weeks.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Local Government Bill.

THE House of Commons, on January 29th, again went into committee on the Local Government Bill. On Clause 86, which gives power to the Minister of Health to reduce grants to councils, if he is satisfied that a council has failed to achieve or maintain a reasonable standard of efficiency in the discharge of its functions relating to public health, Sir L. SCOTT moved an amendment to insert the words "and progress" after "efficiency." He said that the amendment would help the Minister of Health to see that a reasonable standard of progress as well as efficiency was maintained by the local authorities. The amendment, which Mr. Chamberlain accepted, was agreed to.

With a view to defining the public health services which a local authority was obliged to maintain at a reasonable standard of efficiency and progress, Mr. CHAMBERLAIN moved an amendment to insert, after the words "public health," the words "including services relating to maternity and child welfare, lunacy and mental deficiency, and the welfare of the blind." Tuberculosis and venereal disease, he explained, were recognized as being covered by the words "public health," and in order to remove any question as to the others he moved their inclusion in the term. The amendment was agreed to.

Sir L. SCOTT moved an amendment to delete from the clause the proviso that the Minister of Health, when dealing with the question of the reduction of grants, must have regard "to the standards maintained in other areas whose financial resources and other relevant circumstances are substantially similar." The words, he said, might be used to tie the hands of the Minister unduly when dealing with backward authorities. Sir KINGSLEY WOOD said that the amendment would untie the hands of the Minister for the time being altogether, and the operation of the clause would be entirely at his discretion. He could imagine a kind of Minister who might have a very different idea of the standards to be observed in putting the clause into operation. The amendment would also make the point still more difficult from the point of view of the local authorities. The amendment was withdrawn.

On a subsequent amendment by Mr. Lumley, Mr. CHAMBERLAIN said he would consider the possibility of introducing words into the clause to give an opportunity to some outside persons to make representations to the Minister as to the failure of a council to achieve or maintain a reasonable standard of efficiency in the discharge of their public health functions. Such words, however, would have to make it quite clear that the Minister was not dependent on receiving that representation before taking action. At 7.30 the guillotine fell, and Mr. Lumley's amendment was negatived. Clause 86 was added to the bill. Clauses 87 to 92 were also agreed to.

On Clause 94, which mitigates the liability of councils for temporary loans, Sir KINGSLEY WOOD moved an amendment providing that, to meet the case of the distressed areas, the rate for the repayment of loans contracted by Poor Law authorities to be transferred under the bill should be 9d. in the pound instead of 1s. The amendment was agreed to and the clause added to the bill.

Clause 99 provides that any person who, on November 12th, 1928 (the date of the introduction of the bill), shall have been an officer of a Poor Law authority, shall, as respects his office, be transferred to the new authority. Mr. HAYDAY moved an amendment to allow officers appointed after the date of the introduction of the bill to be transferred. He said that an obvious injustice to recently appointed officers would be done if the clause remained as at present. In view of the long periods of distress, and the epidemics of disease which had taken place, quite a number of officers might have been appointed since November 12th, 1928. Sir KINGSLEY WOOD said that it would be generally agreed that a man appointed to a Poor Law office after the introduction of the bill, and therefore aware of the provisions affecting his office, was not entitled to compensation for its loss. The amendment was rejected.

Under the guillotine the clause was added to the bill, as were Clauses 100 to 110 inclusive. Of these clauses, 103 provides for compensation to existing officers, and 104 for superannuation of transferred Poor Law officers.

On January 30th Sir KINGSLEY WOOD moved a new clause declaring that:

"Upon application being made to the Minister by the council of any county or county borough requesting that the contributions of the council towards the expenses of any voluntary association having as its object the promotion of public health services (including services relating to maternity and child welfare, lunacy and mental deficiency, and the welfare of the blind) may be paid directly to the association out of the amount payable as the general Exchequer grant of the council, the Minister may pay such contributions accordingly, and any sums so paid shall be deemed to have been paid as part of that grant."

He said this clause was introduced to meet the criticism that a voluntary association covering the whole of the country would be obliged to collect small sums from many counties and county boroughs. This clause empowered the Minister, if the counties and county boroughs concerned made application to him, to make one payment on behalf of the councils to the association concerned, out of the sums payable as the general Exchequer grant. Answering Mr. Kelly, Sir Kingsley added that the phrase "public health services" covered societies particularly concerned with propaganda against venereal disease. There was no doubt the association to which Mr. Kelly had referred would be able to take advantage of this bill.

Mr. LONGBOTTOM said that, because the Blind Persons Act, 1920, was not compulsory, many local authorities were shelving their responsibility and were leaving to voluntary associations a great deal of the welfare work for the blind. Did this clause prevent a council asking the Minister of Health to pay to societies for the welfare of the blind a certain sum per annum, so that the local authority escaped from its obligation? Sir KINGSLEY WOOD said the clause did not deal with that point. He pointed out that the Minister, under Clause 86, had power to see that local authorities maintained a reasonable standard of efficiency and progress. In considering that question he would also consider the work of the voluntary associations and whether by means of both a reasonable efficiency and progress was maintained.

Dr. VERNON DAVIES asked whether it was necessary for the county to make application to the Minister every year, or whether they could do so for a fixed period, or till notice of cancellation. Sir KINGSLEY WOOD said he would consider what was the best arrangement. When the Act came into operation the Minister proposed to address a general communication to local authorities regarding it, and would direct attention to this clause. In the interval the Ministry would consult the local authorities on the most suitable arrangement. Dr. Vernon Davies could rest assured that the Ministry would regard the best interests of the work.

The clause was then added to the bill without opposition.

Sir KINGSLEY WOOD moved another new clause declaring that a person who had become an inmate of a Poor Law institution for medical or surgical treatment should not, while requiring such treatment, be disqualified on that ground from receiving an old age pension. The clause was added to the bill.

The following new clause was also moved by Sir KINGSLEY WOOD:

As from the appointed day the following provisions shall have effect with respect to functions relating to infant life protection and vaccination formerly discharged by Poor Law authorities: (*a*) Functions under Part I of the Children Act, 1908, shall, elsewhere than in the county of London, be discharged by the councils of counties and county boroughs as functions under the Maternity and Child Welfare Act, 1918, except that where the council of a district have established a maternity and child welfare committee the said functions shall, in that district, be discharged by the council of the district and not by the county council; and (*b*) Functions relating to vaccination shall be discharged by the councils of counties and county boroughs as functions relating to public health.

Sir Kingsley Wood said this new clause was to ensure that the functions in regard to infant life protection and vaccination were imposed on the appropriate authorities and exercised by the appropriate committees of those authorities. At present these functions were discharged by boards of guardians under Part I of the Children Act, 1908, and the Vaccination Act. In the absence of special provisions they might be transferred to county and county borough councils on the appointed day, and so the Ministry proposed that the exercise of these functions should in all cases be undertaken by the maternity and child welfare authorities. It would be satisfactory to give the work to the authorities which employed health visitors, the bulk of whose work related to children under 5 years. It was unnecessary to make special provision for London, since the London County Council and the City Corporation were authorities under Part I of the Children Act, and Clause 52 of this Local Government Bill gave power to the London County Council to transfer functions to the metropolitan borough councils, subject to application to the Minister. As regards vaccination, paragraph (*b*) of the new clause would secure that functions relating to vaccination should be discharged by county and county borough councils as public health functions, and that all matters relating thereto were referred to the health committees, instead of to the public assistance committees. Clause 15 (*f*) provided that vaccination work in London should be transferred to the Common Council of the City and to the metropolitan borough councils instead of to the London County Council. This was in accordance with the wishes of those councils. He thought the clause guaranteed the efficiency of the work in future.

Mr. GROVES said he could support the Minister for the first time in his life. Experience had proved that vaccination did not prevent small-pox, and the step of handing over its enforcement to authorities composed of intelligent men and women would conduce to suppress it. So far as his own borough was concerned, he gave an assurance that they would refuse to impose this fallacy upon the people to satisfy the medical profession.

The clause was added to the bill.

When discussion was resumed on January 31st, Sir KINGSLEY WOOD moved to insert a provision that—

(*b*) Any grants paid or payable in respect of the standard year to the King Edward the Seventh Welsh National Memorial Association for the purposes of sanatoriums shall be treated as if they had been included among the amounts paid or payable out of the discontinued grants; and (*c*) The area for which a voluntary association acts shall be determined by the Minister.

He said these grants included grants in respect of certain capital expenditure. The second part of the amendment was to make clear that in appropriate cases a voluntary association should, for the ascertainment of grants, be deemed to be in one area only.

The amendment was accepted without discussion, and the committee stage ended on February 1st.

Compulsory Closing of Hairdressers' and Barbers' Shops.

A standing committee of the House of Commons, on January 31st, considered and ordered for report to the House, with amendments, the bill which provides for the compulsory closing of hairdressers' and barbers' shops on Sunday. Mr. J. STEWART, the promoter, stated that for reasons of health the bill was desirable. Sir V. HENDERSON (Under Secretary for the Home Office) gave benevolent support to the measure. He explained that hairdressers were not subject to the Sunday Observance Act passed in Charles II's reign. By a decision of the court some twenty-nine years ago, it was held that a barber was not a tradesman. The basis of the argument was that in the days when the original Act was passed a barber was not only a barber, but in many cases a surgeon also, and therefore followed a profession. Consequently it was perfectly legal for him to open on Sundays.

A clause permitting Jewish barbers to close on Saturday instead of Sunday was agreed to, as was another permitting a hairdresser or barber at any time to attend any sick person, either at his residence or elsewhere, for the purposes of that business. Captain CROOKSHANK asked if there was any legal definition of the word "sick." It was a very wide word. If it were necessary to have a medical certificate that a man was sick they would get into a mess. Sir V. HENDERSON said there was no legal definition. The word "sick" covered cases of illness where a person either went to a doctor who considered it necessary that he should be shaved, as was sometimes the case, or cases in which a person was old and infirm, or was confined to the house and unable to help himself, either in regard to cutting hair or shaving. It would be difficult to get a legal definition, and in these matters they must allow for common sense, but before the report stage he would examine what the clause was intended to mean and see if it was possible to introduce words which would make it stronger from the legal point of view. Lieut.-Colonel MOORE moved an amendment to include a disabled person; and Sir V. HENDERSON suggested "sick, infirm, or disabled." There was, he said, a definition of "disabled" in connexion with pensions. The clause was accordingly amended to provide that hairdressers and barbers might attend sick, infirm, and disabled persons, and was then agreed to.

Bills.

A Shops (Hours of Employment) Bill to limit the hours of shop workers, which was introduced by Mr. TAYLOR, was read a first time by the House of Commons on January 30th.

The Coroners Bill, which was introduced by Mr. MORRIS on January 30th and read a first time, proposes to amend the law on inquests in cases where a charge of murder or manslaughter against a person is dismissed by the magistrates while the inquest into the same fatality stands adjourned.

In the House of Lords, on January 29th, the Protection of Animals (Amendment) Bill passed through its committee stage.

In the House of Lords, on February 5th, the Protection of Animals (Amendment) Bill was considered on the report stage.

Enlarged Tonsils: Prosecution for Failing to Provide Medical Aid.—On February 4th Lord E. PERCY told Mr. Viant that he had seen a press report of a prosecution recently initiated by the Wolverhampton education authority against Ernest Henry Gwinnett for alleged cruelty to his daughter, aged 6, by failing to provide adequate medical aid in the matter of enlarged tonsils. He understood that it was stated on behalf of the local education authority that it was not their intention to force an operation on the child, and that all they required was that some treatment should be applied which would be as effective as an operation in curing the condition. He had no information as to the expenditure, if any, incurred by the local education authority in connexion with the proceedings.

Silicosis.—In reply to Mr. Kelly, on February 5th, Sir W. JOYNSON-HICKS said that silicosis was not notifiable, and the only figures on cases of disablement from the disease which he could give were those dealt with under the Refractories Industries Scheme. In 1928 these included 27 cases of partial and 5 cases of total disablement, and 4 deaths. In addition, there were 3 deaths of workmen who had previously been in receipt of compensation. Replying to Mr. Rennie Smith, Sir W. Joynson-Hicks said that a report had been published by the Stationery Office of a medical inquiry recently carried out for the Home Office and Mines Department into the occurrence of silicosis in the sandstone industry. The chief areas concerned were the West Riding of Yorkshire, Lancashire, North Derbyshire, and Durham and Northumberland. It was impossible to give accurate figures of the number of workmen affected, but it was estimated that the figure would not be smaller than 11,000.

Asbestosis among Women.—On February 4th Sir W. JOYNSON-HICKS told Mr. W. Thorne that the senior medical inspector of factories had reported that he was aware of cases of so-called asbestosis of the lungs among women. The effects of asbestos dust were already the subject of a comprehensive inquiry by the medical inspectors, which was being pushed forward as rapidly as possible. As soon as the results of this inquiry were available the question of applying the Workmen's Compensation Act would be considered.

Insurance Companies and National Insurance.—Mr. CHURCHILL told Mr. Shinwell, on February 5th, that he had seen in a weekly journal a suggestion that he was considering an arrangement with insurance companies for handing over control of the national health scheme. He had given a denial to it in answering a supplementary question by Mr. Clynes on January 31st. He was glad to have the present opportunity of repeating the denial. The story was quite untrue. No such project had ever been brought before him or considered by him or any of his advisers.

Ailments of Workers in Artificial Silk.—Sir W. JOYNSON-HICKS, replying on February 4th to Mr. Kelly, said the only two specific ailments which had so far been brought to his notice in the artificial silk industry were conjunctivitis of the eyes and sores on the hands, which were sometimes caused by acid. There did not appear to be any sufficient grounds for scheduling conjunctivitis. Compensation was not payable under the Workmen's Compensation Act unless the worker was disabled for at least three days, and he was advised that even the severer cases of this affection did not as a rule disable the workman for more than one or two days. More prolonged disablement had been due to actual splashes of the acid into the eye, which would constitute an accident within the meaning of the Act. The sores on the hands would appear to be scheduled under the Act as dermatitis or ulceration of the skin produced by dust or liquids, but these sores, if treated promptly, should not incapacitate the workman. The number of cases of injury in this industry was not available.

Influenza in Glasgow.—On February 5th Sir JOHN GILMOUR told Mr. Buchanan that he was aware that there was at present an epidemic of influenza in Glasgow, and a regrettably high general death rate. There was an exceptionally high incidence of acute pneumonia, both primary and influenzal. The Department of Health were in continuous touch with the Public Health Department of Glasgow and were aware of the extent and efficiency of the measures taken in co-operation with the Poor Law and voluntary hospitals to provide hospital treatment and nursing and medical care in the home. Notwithstanding the notification of nearly 1,200 new cases of pneumonia in the week ended January 31st, the waiting list had been cleared and the epidemic, it was believed, had passed the peak. Research into the causation of influenza, its spread in epidemic form, its pathology, and its remedy was being pursued by workers in this and in other countries, and the present outbreak was being watched and studied.

Small-pox.—Mr. CHAMBERLAIN told Mr. Groves, on January 31st, that in the twenty-six weeks ended December 29th, 1928, there were 3,765 notifications of small-pox in England and Wales. In the six months ended December 31st, 1928, three deaths were classed as due to small-pox. For the whole of 1928 the corresponding figure was 53, of which 4 were infants of one month or less, and 31 were of ages ranging from 62 to 89. On February 1st Mr. Chamberlain announced that seven death certificates were received during 1927 in which the word vaccination or vaccinia appeared, and twenty-four during 1928. In 1928 ten of the deaths to which these certificates referred were of infants under 1 year. The figures for 1928 were provisional. He had been told of 16 cases in 1927 and 14 in 1928 in which vaccination had been done within a month of death. Earl WINTERTON, on February 4th, stated that according to the weekly returns furnished by the Government of India the number of deaths from small-pox in British India from January 1st to December 15th, 1928, was 36,184.

Supply of Radium.—Mr. CHAMBERLAIN, in an answer on January 31st to Mr. Robert Morrison, said he had no means of obtaining full information as to the quantity of unused radium in the country nor of its owners. Certain supplies of radium were in the hands of voluntary institutions and private persons. Mr. Morrison further asked whether, in view of the difficulties caused by local authorities and hospitals trying to buy radium, Mr. Chamberlain would take action so that these bodies should not compete against each other for it. Mr. CHAMBERLAIN replied that the question was under consideration by a special committee, whose report is expected shortly.

Heroin and Opium Statistics.—Answering Mr. Cecil Wilson, on January 30th, Sir W. JOYNSON-HICKS said that the total quantity of heroin seized and brought to this country to date from [illegible] was 38,549 oz. It was all disposed of to persons licensed under the Acts, as was 734 kilograms seized at Hong-Kong in 1924, to which reference had been made in a document recently presented to the Opium Advisory Committee of the League of Nations at Geneva. Mr. AMERY, in a reply to Mr. Cecil Wilson, on June 5th, gave the following figures for the consumption of Government opium in Hong-Kong per head of the estimated Chinese population: 1923, 0.51 oz.; 1924, 0.47 oz.; 1925, 0.31 oz.; 1926, 0.25 oz.; 1927, 0.39 oz.

Information concerning Birth Control.—On January 23rd Mr. CHAMBERLAIN told Mr. Thurtle that resolutions in favour of the giving of birth control information at maternity and child welfare centres had been received from 37 local authorities and from 74 other organizations.

[The report of the debate on the committee stage of the Local Government (Scotland) Bill will be published next week.]

Medical News.

MR. H. A. T. FAIRBANK, orthopaedic surgeon to King's College Hospital, will deliver the Lady Jones Lecture in orthopaedic surgery, in the Medical Building of the University of Liverpool, on Thursday, February 28th, at 4 p.m. The lecture, which is open to members of the medical profession, will be on congenital dislocation of the hip, with special reference to anatomy.

THE Sections of Psychiatry and Neurology of the Royal Society of Medicine will hold a special discussion on the prognosis and treatment of general paralysis of the insane on Tuesday and Thursday, February 12th and 14th, at 8.30 p.m. The openers will be Dr. W. H. B. Stoddart and Sir James Purves-Stewart.

AT the quarterly meeting of the Royal Medico-Psychological Association, to be held at the British Medical Association House, Tavistock Square, W.C., on Thursday, February 14th, at 2.30 p.m., the discussion on certain points raised in papers on general paralysis read at the annual meeting by Drs. J. Brander and J. F. Smyth will be resumed.

A CONFERENCE on industrial canteen management will be held at the Hotel Victoria, Northumberland Avenue, London, on Thursday and Friday, February 14th and 15th. In the mornings short papers will be read by experts on various aspects of economical working, and in the afternoons visits will be made to canteens of special interest in the London area. Mr. J. R. Clynes, M.P., will be the guest at luncheon on the second day. The conference has been organized by the Industrial Welfare Society, 51, Palace Street, S.W.1, when further particulars and tickets (price 25s., including luncheons) may be obtained.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Monday, February 11th, Mr. Andrew Wyllie will lecture on The difficulties experienced in the diagnosis of laryngeal diseases, at 5 p.m., and on the following Thursday, at 4.30 p.m., Dr. Gerald Slot will lecture on calcium therapy; both lectures are free, and both will be given at the Medical Society of London, 11, Chandos Street, W.1. A clinical demonstration in gynaecology will be given by Mr. Aubrey Goodwin, at 2.30 p.m., in the Out-patient Department of the Prince of Wales's General Hospital, Tottenham, on Monday, February 11th. Demonstrations will also be given by Dr. J. E. M. Wigley—at St. John's Hospital for Diseases of the Skin, Leicester Square, at 6 p.m., on Tuesday, February 12th—and by Dr. Daukes (on a consideration of various types of ulceration met with in the stomach and intestines), at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1, at 4 p.m., on Wednesday, February 13th. These demonstrations are open to the medical profession without fee. Beginning on February 11th, are a two weeks' course in gynaecology, at the Chelsea Hospital for Women, and a four weeks' clinical course at St. John's Hospital, Leicester Square. There will be an intensive course at the Brompton Hospital, from February 25th to March 2nd, and a comprehensive morning course, limited in numbers, at the Hospital for Sick Children, from February 25th to March 9th. Copies of all syllabuses and information regarding the general course may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Minister of Health recently discussed with deputations representing the Poor Law officers' organizations and the Poor Law section of the National Union of General and Municipal Workers questions relating to the provisions in the Local Government Bill with regard to compensation and superannuation of transferred officers. A substantial measure of agreement was reached, and the Minister promised further consideration of certain other points which were raised.

THE Joint Advisory Committee on River Pollution appointed by the Minister of Health and the Minister of Agriculture and Fisheries to consider the position with regard to the pollution of rivers and streams, and any legislative, administrative, or other measures which appear to be desirable for reducing such pollution, met on January 30th at the Ministry of Health to consider its programme for the immediate future. The committee agreed to devote its next inquiry to the question of the reception of trade and manufacturing wastes into the sewers of local authorities.

DR. S. J. GILFILLAN, medical superintendent of Colney Hatch Mental Hospital, has submitted his resignation, as from April next, on reaching the age of 60 years. He has completed over thirty-one years' service in the London mental hospitals, during more than seventeen years of which he has held his present position.

IN 1928 the number of student registrations in the various French medical faculties, including Strasbourg and Algiers, was 2,891, as compared with 1,349 in 1922.

THE Oxford University Press announces for early publication *Science and Personality*, by Dr. William Brown, Wilde Reader in Mental Philosophy at Oxford; this work contains the Terry Lectures on "Religion in the light of science and philosophy," delivered at Yale by Dr. Brown.

THE report of the Department of Scientific and Industrial Research for the year 1927-28 has now been published by H.M. Stationery Office at the price of 4s. net., postage extra.

THE last annual report of the Institute for Medical Research, Kuala Lumpur, for 1927, refers to the extension of the laboratories then approaching completion. In surveying the work undertaken during that year mention is made of the plasmochin treatment of malaria, which was found effective, though the drug proved more dangerous to administer than quinine; a combination of these two remedies is being tried in subtertian infections. During 1927 the number of patients applying for antirabic treatment was 123; prophylactic inoculation of dogs proved encouraging.

AT the London South-Western Police Court, on February 2nd, Dr. Daniel Evans Powell, High Street, Tooting, who was charged, on a coroner's warrant, with causing the death of Mrs. Doris Ruth Simmons, a Streatham woman teacher, by the use of some instrument, was committed to the Central Criminal Court. He pleaded "Not guilty," and reserved his defence.

REPORTS from 38 States, the District of Columbia, and 8 Canadian provinces show that for the first six months of 1928 small-pox was not quite as prevalent in the United States as during the corresponding months of 1927. In Canada, on the other hand, there were nearly twice as many cases as during the same months of 1927, and nearly three times as many as in 1926.

THE German Society for Internal Medicine and the German Paediatric Society will hold their annual meetings at Wiesbaden from April 8th to 11th and from April 4th to 8th respectively. A conjoint meeting of the two societies will be held on April 8th to discuss the preventive inoculation and serum treatment for measles, scarlet fever, and diphtheria, introduced by F. Neufeld of Berlin, M. v. Pfaundler of Munich, H. Schottmüller of Hamburg, and U. Friedemann of Berlin. The dynamics of valvular disease of the heart and the treatment of loss of compensation in valvular disease will also be discussed by the Society for Internal Medicine, and the other subjects for discussion by the Paediatric Society will be the pathology and treatment of eczema and non-purulent encephalitis in children.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863*, and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

INHALATION THERAPY.

DR. A. A. E. NEWTH (Attleborough) asks if any readers have had experience in the [illegible] and asthma by means of the [illegible] inhalation therapy. The [illegible] especially valuable.

TREATMENT OF ABDOMINAL PAIN IN HEPATIC CIRRHOSIS.

"G. P." asks for advice on the treatment of severe abdominal pain (presumably due to perihepatitis) in alcoholic cirrhosis of the liver. The pain is made much worse by lying down; consequently the patient seldom goes to bed. He is an advanced case, but there is no ascites, and the Wassermann reaction is negative. Apart from the general treatment of his condition, counter-irritants, heat, and numerous analgesics have been tried; the only drugs found to give relief were the opium preparations in large doses, and even this relief was evanescent.

TREATMENT OF MYXOEDEMA.

"W. R." would be grateful for any suggestions for the treatment of a married woman, aged 40, who had hysterectomy performed seventeen years ago, and has had typical myxoedema for at least nine years. This has in the past responded well to thyroid extract, but now even small doses cause anginal pains which persist for some time after it is discontinued. The blood pressure and urine are normal. The heart also, so far as physical examination can determine, is normal.

INCOME TAX.

Travelling Expenses.

"R. R." inquires as to whether he can deduct the expense of travelling from his residence to the institute at which he holds an appointment.

*** "R. R." points out that this expense is similar to that incurred by a medical man in visiting his patients, but unfortunately the emoluments arising from the appointment are assessable under Schedule E and the rules relating to expenses under that schedule are in some respects more stringent than those relating to Schedule D, which deals with general professional earnings. According to the decided cases, the expense of travelling between residence and place of employment are not admissible deductions, inasmuch as they are incurred prior to, and not "in the performance of," the duties of the office.

Purchase of Practice.

"H. M.," who has a private income, purchased a small practice in June, 1928; how should his return be made for 1928–29?

*** The return made before the purchase of the practice is, of course, rendered obsolete by that transaction. "H. M.'s" liability in respect of the practice will be on three-quarters of the net earnings for his first year to June 30th, 1929—or, if he prefers, he can make up his accounts as at March 31st or April 5th, 1929, and reckon the amount so arrived at as the sum liable to tax for 1928–29. The cash basis is not acceptable for such an account, and "H. M." will have to bring into his statement of receipts and expenses the value of the debts due to him and the amount of outstanding unpaid expenses at the end of the period taken. In calculating expenditure on drugs a deduction will have to be made from the total payments to cover drugs purchased but still on hand.

LETTERS, NOTES, ETC.

EXAMINATIONS AND THE GROWING CHILD.

MR. H. C. DENT, B.A. (Chairman, English Section, New Education Fellowship), writes: My attention has been drawn to your leading article of January 19th (p. 11[illegible] reporting upon Sir Michael Sadler's address to the New [illegible] on "Examinations." This address marks [illegible] of an exhaustive inquiry into the subject of examinations by the New Education Fellowship, which will attack the subject in the main from the point of view of modern psychology, and consider the effect of preparation for external examinations upon the physical, mental, and spiritual growth of the child. We feel that the medical profession can supply us with evidence available from no other source, and I therefore crave the indulgence of your columns to broadcast an appeal to members of your profession. Our English representative is Mrs. S. Platt, who will be pleased to receive at the headquarters of the Fellowship (11, Tavistock Square, W.C.1) any information bearing upon the subject. She is due to present a preliminary report in August, but, as much information is already to hand, would prefer to receive any communications before the middle of March.

POST-VACCINAL ENCEPHALITIS: VACCINAL IMMUNITY.

DR. R. W. JAMESON (West Wickham, Kent) writes: In your issue of February 2nd your reporter's condensation of my remarks at the Epidemiological Section of the Royal Society of Medicine somewhat misrepresents my views. I did not suggest that post-vaccinal encephalitis was not even uncommon in infants, but that we have not sufficient evidence to warrant the assertion that it is less common in infants than in older children. Another remark attributed to me should be inverted: vaccinal immunity is more lasting against the trivial variola minor than against the virulent variola major, as one would expect.

ANAESTHESIA FOR TONSILLECTOMY.

DR. HEYMANN LEVIT (Johannesl[illegible] the recent discussions on anaesthesia for [illegible] During the past nine months I have used an apparatus for ether anaesthesia which consists of a 1/6-h.p. motor pumping air into a bottle containing ether. The vaporized ether is conducted from the bottle by means of a tube to a Boyle's bag with valves and face-piece, the latter being used in the same way as for the administration of nitrous oxide gas. I find in the case of children that on an average five minutes' total induction is sufficient for the removal of tonsils and adenoids, whatever may be the method of operation, and that this leaves ample time to attend to haemorrhage. In the case of an adult the anaesthetic may be continued via the nose or a small tube in the corner of the mouth.

THERAPEUTIC VOMITING IN INTESTINAL OBSTRUCTION.

DR. CHARLES J. HILL AITKEN (Kilnhurst, nr. Rotherham) writes: The left inguinal hernia in an aged person became immovable and very tender. Obstruction was complete and vomiting constant. Operation was refused. I encouraged the patient to drink lots of water and to vomit (see "Therapeutic value of vomiting in intestinal obstruction," Sir Charters Symonds, *Practitioner*, March, 1923), controlling the vomiting very occasionally by morphine. For ten days her general condition remained good and then her heart failed and she died on the twelfth day.

CHEMICAL WARFARE.

AT a meeting of the Royal Sanitary Institute, held on February 1st to discuss chemical warfare and anti-gas protection, Lord Halsbury, who presided, spoke of laboratories in ten or eleven countries all engaged in intensive research on the production of more devilish gases, and the possibility of liberating hundreds of tons of gas over London from a fleet of aeroplanes in such a way that the gas would be canalized by the valley of the Thames and waft destruction from the Wandle to Barking Creek. His idea was that it was better to have some degree of panic now, when it might result in organized measures for the public safety, than to have panic on the event, when it would add to the difficulty of the situation and assist the enemy's purpose. Major F. R. Humphreys, late R.A.M.C.(T.), and R.A.F., forecasted the possible nature of the attack and the means of safety. He classified war gases as vesicants (chiefly mustard gas and the American preparation, lewisite); lung irritants, of which phosgene is an example; sensory irritants, or smokes, mostly organic compounds of arsenic-arsines, considered by many to be the most dangerous of war gases, because of the severe injury to the bronchial tubes and lungs brought about by a very small dose; lacrymators, and, finally, direct poisons of the nervous system, of which hydrocyanic acid is the chief example. He considered that mustard gas was the most likely to be employed in an early attack on London. To meet a sudden and unpreventable attack preparations must be in existence and defence ready, and he proceeded to outline such an organization. It would consist of a band of persons physically fit, trained, and equipped with gas masks and special clothing and utensils, and capable of mobilization at the shortest notice. It would work in four sections. The duty of the first section would be to look after the safety of the people in the gassed zone, either by evacuating them, or, in less dangerous parts, supervising the preparation of gastight rooms, distributing printed instructions, and the like. The second section would consist of those who had the very important and dangerous duty of clearing gas from the poisoned area; the third would arrange for the decontamination of those who had been near the gas and were a danger to themselves and their neighbours, while the fourth, which would naturally fall to the voluntary aid societies, would carry out first aid to the gassed and wounded and transport them to hospital. With regard to the sealing up of rooms, Major Humphreys said that if the people in the room kept quiet and if naked lights were not burnt, a space of about 200 cubic feet per person in a room 10 ft. high would maintain life for twelve hours. This would allow time for clearing the streets from gas and for removal of persons to a safe locality. The clearing up of the gassed area would be effected in part by natural forces—wind, rain, and sun—but supplemented by the washing down of the streets and houses, and by covering up with earth or sawdust mixed with effective chemicals, all places where poison-laden liquids had soaked in. He suggested that the education of the public in these and other defensive measures must be the work of the local authorities, who must also provide special protection for vital points, such as water supplies, docks, and food [illegible] as well as hospitals and first-aid shelters. Major W. Richardson Gafwey, R.A.M.C., reminded the audience that in France, in areas soaked with mustard gas, with about three million men engaged, the total mustard gas casualties were 160,000 [illegible] average death rate was only 2 per cent., and the permanent invalidity rate about the same. He added that civilians living in the gassed zone in France who took the ordinary precautions of going into their houses and shutting tightly their doors and windows very largely escaped.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals [illegible] be found at pages 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 85.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

126. Infective Endocarditis associated with Congenital Heart Disease.

M. WYBAUW (*Bruxelles-Méd.*, January 6th, 1929, p. 283) demonstrates several important features of congenital heart disease in his description of a patient who died at the age of 28 from infective endocarditis. The patient had been subject to cyanosis on effort since infancy, and first sought advice when 18, on account of increasing symptoms and sickness on exertion. A systolic thrill and murmur were heard over the precordium, their greatest intensity being in the third left intercostal space. The orthodiagram revealed enlargement of the right side of the heart, and a diagnosis of congenital pulmonary stenosis with patent interventricular septum was made. With rest and care the patient's condition improved so that he led a fairly normal life for eight years; he then noticed increasing breathlessness and fatigue, and an examination showed enlargement of the heart and pyrexia, while a blood culture revealed the presence of *Streptococcus viridans*. The only embolic phenomena which occurred before death five months later were splenic and intestinal infarctions. At the necropsy hypertrophy and dilatation of the right auricle and ventricle, with stenosis of the pulmonary orifice, were found. A large communication existed between the ventricles, and all the valves showed vegetations, those of the right heart being most extensive. The author comments upon the tolerance shown by the patient with such severe lesions, and remarks that the case illustrates the liability of congenitally abnormal valves to become the seat of malignant endocarditis. Probably the pulmonary valve was the first to be affected, while infection of those of the left side of the heart was facilitated by the presence of a septal defect. Throughout the illness constitutional effects predominated over those due to the cardiac lesion.

127. Accidental Treponemiasis.

J. D. ALLAN GRAY (*Ann. Trop. Med. and Parasitol.*, November 9th, 1928, p. 273) describes an infection by *Treponema duttoni* acquired accidentally in the laboratory. Four attacks followed an infection which seems to have supervened on contamination of the fingers with infected mouse blood, and it is probable that between the fourth and fifth attacks there was renewed infection by the bite of a diseased mouse. The first attack is thought to have been due to the spirochaetes penetrating the unbroken skin; the second is attributable either to the bite causing infection with spirochaetes already on the skin from contamination with infected blood, or directly to the animal's mouth. The clinical condition which followed was severe: there were eight bouts of pyrexia and two abortive attacks, but at no time was there any enlargement of the liver or spleen. The afebrile intervals were of irregular duration, the longest lasting twenty-seven days and the shortest seven. Spirochaetes were not seen in the blood at any stage of the infection, but inoculation of mice during the fifth attack, and thirty-two days after the last, revealed the infection. Treatment by novarsenobillon was unsatisfactory; 0.6 gram neither cut short the fever nor prevented relapses. No antibodies were found in the blood, and the patient's serum did not protect mice. A considerable bibliography is given.

128. Diphtheria and Quinsy.

G. GAUTHIER (*Thèses de Lyon*, 1927-28, No. 31) states that cases occasionally occur in which diphtheria is accompanied by, or more frequently succeeds, a tonsillar or peritonsillar abscess. Such cases are usually found in adults and should not be confounded with the pseudo-phlegmonous form of diphtheria. This clinical form usually involves a very serious prognosis, as shown by a number of sequels and prolonged attacks. The pathogeny of the condition undoubtedly consists in the association of the diphtheria bacillus with other organisms, especially the streptococcus. It must also be taken into consideration that diphtheria is developing in a soil already weakened by a previous infection. Treatment should consist in large doses of antitoxin, which should be given as soon as possible. Moreover, the utmost care should be taken to prevent diphtheria patients from coming into contact with individuals suffering from quinsy or subject to recurrent attacks of this disease. The thesis contains the histories of seventeen cases, the ages of the patients ranging from 15 to 36.

129. Bimanual Palpation of the Thorax.

A. SAVULESCO (*Bull. et Mém. Soc. Méd. des Hôp. de Bucharest*, November, 1928, p. 336) suggests a new clinical method for the observation of local fremitus. While these vibrations are usually easily palpable in men, they are often difficult to detect in women, children, and those who have soft voices. If one hand is placed on that part of the anterior aspect of the chest which is to be examined, and the other is pressed over the corresponding area posteriorly, vocal fremitus is greatly magnified. By this means vibrations may be felt in patients who show none by other methods. The author illustrates his technique by describing two cases. In the first, a young woman at the onset of pneumonia, no fremitus was felt until the bimanual method was applied, and this revealed diminished vibration over the area in which tubular breathing subsequently developed. The second patient, a boy with a penetrating wound of the thorax, had several rigors ten days after his injury. No vocal fremitus was elicited anywhere over the thorax until bimanual compression was tried, when it was felt at all areas except at the right base. The presence of fluid was thereby indicated, and subsequent exploration revealed an empyema.

130. Recovery from Staphylococcal Meningitis.

F. BEZANÇON, R. WEISMANN-NETTER, and DESTOUCHES (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, No. 35, December 20th, 1928, p. 1764), who record an illustrative case, state that meningitis is a rare localization of staphylococcal infection. Whether early or late it always aggravates the prognosis, and in all previously recorded cases the issue has been rapidly fatal, with the following exceptions: (1) cases of staphylococcal meningitis without septicaemia properly so-called, as in the two cases following otitis reported by Lortat-Jacob and Grivot in 1920; (2) meningeal conditions occurring in staphylococcal infection, as in the case recently recorded by Faroy and Marchal. The present case was that of a woman, aged 30, admitted to hospital with well-marked meningitis and labial herpes. Lumbar puncture gave issue to a turbid fluid, and antimeningococcal serum was injected intrathecally and intramuscularly. No benefit was derived from the treatment, and examination of the blood and cerebro-spinal fluid showed the presence of *Staphylococcus aureus*. Recovery finally ensued after the occurrence of cutaneous complications in the form of non-suppurative nodules and actual abscesses, pyelitis, and spondylitis.

Surgery.

131. Bone Sarcoma.

A. KOLODNY (*Cancer Rev.*, January, 1929, p. 1) remarks that the trauma which is frequently associated with the appearance of bone sarcoma may play an important part in its etiology. Having investigated 800 cases (see *Journal*, 1927, vol. ii. p. 358), he now defines five groups: osteogenic, Ewing's, myeloma, unclassified sarcomas, and giant-cell tumour. An osteogenic sarcoma is a sarcomatous tumour derived from the osteoblasts; thus it is an osteoblastoma somewhat as a carcinoma of the skin is an epithelioma. The most frequent cytological element in this sarcoma is the small spindle cell with a small, hyperchromatic nucleus and indistinguishable borders. The chief difference between this type of sarcoma and other malignant tumours lies in its intercellular substance, of which there are five types: hyaline, osteoid, cartilaginous, myxomatous, and osseous. Extreme vascularity is a characteristic of these neoplasms. Osteogenic sarcoma is primarily a disease of the young, and occurs in most bones, the metaphyses being the seat of predilection. Metastases appear in various organs, but most frequently in the lungs. Pain, usually preceded by tumefaction, is the first symptom. The prognosis is grave, and most cases terminate fatally. Operation has been the method of treatment, though radiation may prove beneficial. Ewing's sarcoma favours the smaller bones of the extremities and skull, and usually occurs in the last half of the first and first half of the second decades of life. The typical cell is small and polyhedral, with a round, oval, or slightly elongated nucleus and scanty, clear cytoplasm. Metastases in the skull are frequent and early, and pulmonary ones are also very common. This sarcoma yields rapidly to radium or x rays, but usually recurs and slowly becomes refractory to further radiation. Operation combined with radiation is probably the best

treatment. Myeloma favours the mid-portion of the long bones and the flat bones, and usually affects men between the ages of 40 and 60. Most myelomas are composed of non-granular mononuclear cells with a basophilic protoplasm. This tumour is readily affected by radiation, and, though there is a tendency to recurrence, the prognosis is much better than in other bone sarcomas. Under unclassified sarcomas are included angio-endothelioma and extraperiosteal sarcoma, both of which are rare. The former springs from the endothelium of the vascular channels, and histologically resembles an adenoma. The latter arises from the fibrous layer of the periosteum, and histologically is a fibrosarcoma. Pulmonary metastases may occur. Surgical removal of these growths should be followed by prophylactic radiation. Giant-cell tumours occur between the ages of 15 and 25, are usually situated in the epiphyses of the long bones, and are generally solitary. This growth consists of the giant cells and a stroma of various-sized blood spaces and thin-walled capillaries in a net of spindle, round, or polygonal cells with large vesicular nuclei. Pain and trauma are frequently to be noted in its history, and the *x*-ray picture is characteristic. Giant-cell tumours are benign, and readily amenable to operative measures as well as to prolonged and systematic radiation; complete cures are the rule.

132. Plastic Surgery of the Head.

F. L. LEDERER (*Arch. of Oto-laryngol.*, November, 1928, p. 531) describes a method of repairing defects in the face and ears of patients who have lost tissue from disease, congenital malformation, or injury. He remarks that those whose deformity is due to syphilis present the most difficult problem because the tissues are devitalized, the circulation is disturbed, and there is a great deal of scarring. The author finds that in many of these cases where several operations have been performed the result is a heavy-looking mass of tissue which does not present a very good likeness to the missing organ. He has developed a method of making artificial organs which are specially designed to match the opposite member or to blend with the general appearance of the patient. A plaster cast of the region to which the artificial organ is to be applied is first prepared, and this serves as a mould for the under surface of the new organ. In the case of the ear a cast of the opposite ear is obtained, and a positive cast is made of this; a wax ear is moulded to replace the missing one, the positive cast being used as a model. When the wax ear is ready a metal mould is made, and from this any number of false ears may be obtained. For the nose a mould is prepared to fit the cast of the malformed region, and great help is derived from photographs of the patient before the deformity occurred. The final ears and noses are made of a mixture of gelatin and glycerin; the coloration is procured by adding white oxide of zinc and carmine-red powder. Water must be rigorously excluded from the mixture. A little salicylic acid added helps to keep the material fresh, and the addition of potassium bichromate renders it possible to wash the organ in warm water. After the model has been made it can be tinted to get a perfect match. The mould is kept and a series of fresh models prepared as required. This is necessary since the models do not last more than two weeks each. The advantage of these models is that they are lifelike, light, and elastic; when once the mould has been made they are very cheap.

133. Treatment of "Mixed" Parotid Tumour.

A. LÁNG (*Zentralbl. f. Chir.*, December 22nd, 1928, p. 3210) comments on the well-known frequency of recurrence of "mixed" parotid tumour after attempted removal and the technical difficulties of the operation. The facial nerve cannot escape injury or division, while the proximity of the internal carotid renders any attempt at complete ablation very dangerous. Láng recommends radium treatment when the patient's general condition is good and the tumour is localized. He reports the case of a man, aged 68, who was admitted to hospital with a swelling of the left cheek; a tumour behind the left ear had been removed seventeen years previously. The swelling had been growing rapidly, and an ulcer developed in front of the left ear a day before admission. In this region there was a soft painless tumour as large as a hen's egg and blending with the parotid gland; section showed that the growth was an adeno-carcinoma. Intensive radium therapy was employed, in the form of superficial irradiation over five fields, in addition to radium needles buried in the tumour. Five days after the commencement of treatment large necrotic masses were removed, the tumour was appreciably smaller, and the ulcer began to heal. In six weeks the tumour had disappeared and the ulcerated surface was covered by normal epithelium, leaving a well-marked scar. Láng records this case to show that a recurrent adeno-carcinoma of the parotid may be cured by radium therapy, with a good cosmetic result.

Therapeutics.

134. Lead Treatment of Cancer.

G. LOEWY and J. LOISELEUR (*Bull. du Cancer*, November, 1928, p. 549) have used glycogen as a vehicle for the colloid lead oxide injected intravenously in their experiments and treatment. This solution of colloid [illegible] said to be stable and can be ke[illegible] dose was first worked out on mice, rats, and dogs, and, finally, during the past two years they have been treating patients with the same compound. In a series of 21 almost hopeless cases which had been given up as inoperable or incurable the results obtained were not very promising. The authors report that the drug, associated with glycogen, is well tolerated; there is little effect on the liver, and usually signs of lead poisoning do not appear until several doses have been given. Anaemia, produced in some cases, was readily controlled and improved by liver treatment. The authors claim no clear case of cure, and observe: (1) The lead had no effect on four cases of breast tumour, but oedema and softening were produced in tumours of soft parts. (2) Two patients with osteogenic sarcomas showed no signs of reduction of the tumours. (3) No result was noticed in one case of disseminated melanotic sarcoma. (4) One patient with cancer of the oesophagus did not lose his dysphagia, but, rather curiously, had no pain. (5) Arrest in the growth of the tumour was noticed in four patients, three of whom had recto-sigmoid carcinoma and the fourth cancer of the stomach; each had previously had a colotomy or gastro-enterostomy operation. These patients were also treated with liver for their anaemia, with results so striking that it was difficult to apportion to the lead its real value in improving the general condition of the patient, but the authors think that it may play a distinct part in the very great general improvement, especially so because in several cases the injection of the lead was followed by local pain, oedema, and congestion, and, in ulcerating tumours, by some haemorrhage. The relative harmlessness of the treatment with lead oxide and glycogen has encouraged the authors to continue their research.

135. Chemotherapy of Pulmonary Tuberculosis.

DISCUSSING chemotherapy in tuberculosis of the lungs, J. TROTOT (*La Vie Méd.*, January 10th, 1929, p. 17) asserts that the tuberculous cell is nourished by osmosis, and by the same means impregnates the normal cells with its toxins. Therefore, in order to be efficacious, a chemical agent must have sufficient stability to be carried, without decomposition or modification, to the perituberculous healthy cells; it must penetrate the giant cell by osmosis and there exert its action. Of the various chemical agents which may be employed, the author deals only with those which restore calcium. Many conditions point to the coincidence of tuberculosis and decalcifying states; among these are the calciuria in cases of this disease, and the presence of chalky tubercles in the aged, pregnancy, enteritis, and gastric hyperacidity. Recalcification is not a new treatment, and is based on two principles: avoidance of the loss of lime by diminishing the causes of digestive acidity; and furnishing the organism with such lime salts as are capable of being fixed in the tissues—a difficult procedure. Some authorities have advocated the use of insoluble salts, as bone phosphate and calcium carbonate, in association with other salts; others advise the indirect calcifiants accompanying lime in the organism, such as phosphoric acid and phosphorized lipoids. Intravenous injections and inhalations of lime salts have also been recommended. Calmette, however, has found that experimental results do not support the[illegible] suggestions; Blum, Dolaville, and Caulaert have reported that lime administration increases acidosis and is in reality a decalcifier. Trotot agrees with [illegible] vomiting of nurslings he has found. [illegible] tion of one or two large spoonfuls of lime water produces the best effects on the nutrition and development, possibly by virtue of its alkalinity; and in both adults and children he employs lime only in this simple and inexpensive form.

136. A Synthetic Substitute for Ephedrine.

THE search for a more easily available source of ephedrine, or a cheap but yet effective substitute, led H. MILLER and G. PINESS (*Journ. Amer. Med. Assoc.*, October 6th, 1928, p. 1053) to an unsuccessful attempt to obtain it from several varieties of the Californian ephedra, and to endeavour to synthesize it. Alles, working in their laboratory, has synthesized a phenyl-ethanolamine, on which he has recently reported. This may be more specifically described as a racemic a-phenyl-b amino-ethanol sulphate. The base is closely related chemically to tyramine, epinephrine, and ephedrine, and has been known for some time, though Alles's method of preparation is new. Alles claims that, as compared with ephedrine, this sulphate

has an initially greater and finally comparable blood pressure effect on rabbits; that these initial changes more resemble those following epinephrine than those following ephedrine; that the duration of blood effect closely resembles that of ephedrine; and that the toxicity for guinea-pigs is one-third as great as that of ephedrine. Clinical studies have been made as to its effect on blood pressure, in mydriasis, bronchial asthma, hay fever, and other nasal conditions. The preparations used were the crystalline form, in a 2 or 5 per cent. solution, to which 0.5 per cent. chlorbutanol was added as a preservative. The authors report that clinical evidence points to the inactivity of this sulphate on oral administration, and to an advantageously weak pressor, but disappointingly weak broncho-dilator, effect on hypodermic injection. The drug is apparently most useful as a topical application in the nose, where its activity is said to be in every way comparable with that of ephedrine.

137. Synergism of Magnesium Sulphate and Morphine.

REPLYING to criticisms of his work and statements concerning the synergism of magnesium sulphate and morphine, J. T. GWATHMEY (*Journ. Amer. Med. Assoc.*, December 8th, 1928, p. 1774) declares that he never stated that smaller doses of morphine could be used with magnesium sulphate to overcome pain, but that the addition of the latter increased the value of the former. The classic case in which the potentiation of morphine was first firmly established, the clinical results in 84 cases in two different hospitals, and the experiments of Gwathmey and Hooper are cited in support of this contention. Gwathmey affirms that the synergism of these two substances has been definitely proved clinically in both obstetrics and surgery, the value of morphine having been increased from 250 to 500 per cent. Experimentally, this synergism is life-saving with animals when ether is used as an anaesthetic; clinically, it is also life-saving, decreasing both morbidity and mortality, and it should be used with all methods of anaesthesia and analgesia. Records of nearly 20,000 cases are said to show that it is far superior to hyoscine. The synergism of magnesium chloride with amido-pyrine, sodium salicylate, and acetyl salicylic acid has been proved by Barbour and Winter. The synergism of magnesium sulphate and ether has been proved for various animals and man, and is of practical importance in relation to the synergism of magnesium sulphate and morphine. The probability is that magnesium sulphate synergizes with almost any drug with which it is compatible, by prolonging its action, deepening its effect, reducing fever, or acting in other ways.

Neurology and Psychology.

138. Early Diagnosis and Treatment of Insanity.

J. V. BLACHFORD (*Bristol Med.-Chir. Journ.*, Winter, 1928, p. 253) discusses various types of mental disorder at different physiological periods, and those connected with poisons, alcohol, and syphilis. The first one considered is the child of the "young criminal" type. The symptoms occur before puberty, take various forms, and the children are of a neurotic temperament. Blachford maintains that these patients should be treated kindly but very firmly, and punishment should be an inevitable consequence of misdoing. Dementia praecox, a mental disorder of puberty and adolescence in which there is said to be always a bad family history of some neurosis, begins between the ages of 15 and 25, and the first sign is aversion from parents and relations. In the early stages treatment should be stimulative, with attention to the bowels and food; when the disease is established detention in a mental hospital is advisable. The prognosis, unfavourable in all cases, is better in females. Epilepsy is a frequent cause of insanity during puberty and adolescence, and in most of these cases a history of some familial neurosis will also be found. That mental trouble is more likely to follow *petit mal* than *grand mal* appears to be a mistake. Regarding treatment, emphasis is laid on the remarkable efficacy of luminal. The symptoms of insanity of pregnancy are those of despondency. Careful nursing and watching is necessary, and, if the patient becomes worse, mental hospitalization must be considered. In puerperal insanity a brisk purge should be given, and if this with appropriate treatment produces no improvement the patient should be certified without delay. Climacteric insanity may arise long after the menopause, and is often complicated by alcoholism. The symptoms are usually those of self-accusatory depression. Beneficial drugs are *dial*, *paraldehyde*, and bromidia, though institutional treatment may become necessary. In delirium tremens all alcohol should not be stopped, though the amount should be considerably reduced; chloral hydrate is almost a specific for this condition. Syphilitic mental disorder may be divided into general paralysis and cerebral syphilis. Early signs of the former are a seizure, first attack of subacute mania between 30 and 50, lapses of memory, exaggeration of natural characteristics, undue energy, inability to concentrate, and rashness in business. Early treatment is most important and should include rest from business. Cerebral syphilis, unlike general paralysis, is amenable to antisyphilitic treatment. There are three clinical types: some cases simulate general paralysis, others resemble hemiplegia with or without loss of speech, while in the third variety there is a rapid onset of amaurosis with dementia. Three typical cases are reported. Generally speaking, in the early stages of mental disorders the treatment should be stimulative. In very acute cases beneficial drugs are hyoscine hydrobromide, paraldehyde, sulphonal, veronal, medinal, and dial ciba. In irritable, restless melancholia tincture of opium with sp. aether. sulph. is safe and valuable. Chloral hydrate is a dangerous drug, especially in cardiac cases. Treatment by psycho-analysis is not approved by Blachford.

139. The Symptomatology of Tumours of the Temporal Lobe.

A. KOLODNY (*Brain*, October, 1928, p. 385) remarks that the possibility of resection of a large portion of the right and even of the left temporal lobe without noticeable functional disturbance makes an early localization of a temporal lobe tumour imperative; he discusses the symptoms noted in 38 cases of tumours confined to this lobe. No attempt is made to formulate a definite temporal lobe syndrome, and the symptoms are merely enumerated in their order of frequency. Headaches, which occur in all the patients, are of no localizing value; local pain or tenderness (noted in 26 per cent.) is of greater importance, and is probably due to local pressure on the branches of the trigeminal nerve. Vomiting, present in half the cases, is merely due to increased intracranial pressure, and has no localizing significance. Definite oedema, seen in the optic discs of 86 per cent., was of assistance in indicating the side affected in only the incipient stages of the papilloedema. In temporal tumours sphincter disturbances are merely a symptom of intracranial pressure; they were present in 20 per cent. of the present series. In frontal growths they are probably due to psychic disorders. Psychic disturbances, if accompanied by other signs, may aid in localizing the tumour. Defects of memory in half the present cases were equally noted in frontal tumours, when only recent events were forgotten, while in temporal tumours both past and recent events are involved. Changes in personality, hyperaemnia, and mental confusion are of little localizing value except in differentiating subtentorial tumours, for in these they rarely occur. That psychic disturbances are due to lesions of the left hemisphere in right-handed persons is not supported by clinical facts. Fits, a relatively early symptom in half the cases, were of localizing value in only 40 per cent., uncinate fits and dreamy states are merely of localizing value, but concomitant visual hallucinations indicate the side affected when occurring in a part only of the visual field. The most constant motor and sensory symptom was a contralateral lower facial weakness. The abdominal reflex was a decisive lateralizing sign in 39 per cent., and the plantar response in 45 per cent. A cerebellar type of gait was noted in only one case, and the existence in the temporal lobe of an organ of balance was not substantiated by the findings. Visual defects of lateralizing importance were found in only 18 per cent. Disturbances of hearing have little localizing and no lateralizing value, but increasing impairment of hearing in both ears is suggestive of a temporal lesion. Disturbances of smell and taste are of no diagnostic significance. Disorders of speech in right-handed persons assist greatly in local diagnosis, though aphasia is not of so much diagnostic importance as is believed. Oculo-pupillary changes (myosis or mydriasis and ptosis) were observed in 55 per cent. These are transitory; they recur from time to time, and finally become permanent. The commonest alteration is in the size of the pupil; changes of shape were noted only four times. Complete oculomotor paralysis was not observed. Involvement of the ipsilateral abducens was present in seven cases; in two of these the paresis was bilateral, but only the ipsilateral nerve was completely paralysed.

140. Treatment of Syringomyelia.

J. VITEK (*Bruxelles-Méd.*, January 13th, 1929, p. 311) describes a new procedure which can replace operation, and which, in combination with radiotherapy, is thought to mark an advance in the treatment of syringomyelia. This method, termed endomyelography, consists in the injection of $\frac{1}{2}$ to 1 c.cm. of lipiodol by a simple dorsal puncture over the medullary segments where the cavity is the most extensive. After the injection the fluid in the syringomyelic cavity can be evacuated, and thus a decompressive puncture of the ependymar liquid is performed. The following is the technique employed. With the patient lying on his right side,

under local anaesthesia, the needle is pushed into the subduramatral space exactly in the middle line; the spinal fluid will then commence to flow. The needle is further advanced till the posterior columns of Goll and Burdach are touched. A momentary pain shows that passage across these columns and entry into the ependymar space has been made, when the syringomyelic liquid always commences to flow. The lipiodol is then introduced and decompression follows. In the three cases reported this operation caused a marked and rapid amelioration of the spasticity in the lower limbs and of the pains in the upper ones, which was probably due to the pressure of the intra-ependymar liquid. This method has been employed with equal success in four cases by Jirásek. Vitek claims that this procedure, which is perfectly tolerated by the patient even though large amounts of lipiodol be used, is more advantageous than laminectomy and intercolumnar incision. It does not forbid or complicate a subsequent operation should such become necessary.

Obstetrics and Gynaecology.

141. Prevention of Foetal Mortality.

A. COUVELAIRE (*Paris Méd.*, December, 1928, p. 567) reports that in a series of 1,000 births 14 foetuses perished during gestation and 19 during labour; 12 infants succumbed within the first three days of life. He believes that the cause of death has been discovered in little more than two-thirds of such cases, and is most commonly syphilis, albuminuria, eclampsia, chronic renal disease, or diabetes. Tuberculosis does not kill the foetus in the uterus. Treatment of the syphilitic mother by arsenic, bismuth, or mercury has considerably reduced the foetal mortality, the results being better in cases where the maternal infection was recent. Couvelaire considers that cases of eclampsia not preceded by albuminuria or a high blood pressure are more frequent than was thought; when the precursory symptoms are detected eclampsia can be successfully avoided and the foetus saved by proper treatment. Nephritis in the mother, accompanied by a high blood pressure, gravely prejudices the unborn child, and syphilis is not uncommonly the primary cause. Such an infection may be difficult to prove, and the author agrees with Bar and Daunay that the value of a negative serological reaction in pregnancy is particularly doubtful where the infection is a long-standing one. Couvelaire adds that the greatest fall in the foetal death rate has occurred in properly treated cases of syphilis and albuminuria; he emphasizes the importance in this respect of ante-natal supervision.

142. Early Diagnosis of Cancer of the Cervix.

E. PREISSECKER (*Zentralbl. f. Gynäk.*, January 5th, 1929, p. 11) states that even in recent times early carcinomata of the cervix are not very infrequently found accidentally in systematic examination by section of cervices which clinically had not been suspect. For this reason, and since improved results in treatment of cancer of the cervix are dependent on the earliest possible diagnosis, careful search should be made for areas of leucoplakia, which in some instances are small, incipient carcinoma. In the II Universitäts-Frauenklinik at Vienna the search for such growths is aided first by the application of iodine, secondly by colposcopic observation, and thirdly by microscopical examination of scrapings from the area which the first two methods of investigation seem possibly to incriminate. After painting with Lugol's iodine solution, carcinomatous areas, as shown by Schiller, do not stain. The non-staining areas are examined, with a magnification of fifteen times or more, by a colposcope which is a modification of Hinselmann's instrument. Leucoplakia thus detected is suspicious, but not conclusive, of malignancy. Preissecker describes three cases giving identical colposcopic appearances, in which microscopic examination revealed carcinoma, condyloma, and late syphilitic leucoplakia respectively.

143. Ovarian Sclerosis and Tuberculosis.

M. LAEMMER (*Bull. Soc. de Thér.*, December 12th, 1928, p. 253) records three illustrative cases, in women aged 18, 24, and 31 suffering from amenorrhoea, which had been unsuccessfully treated by a combination of thyroid and ovarian extract. All the patients showed various manifestations of external tuberculosis, such as cold cervical abscesses, chronic chilblains, and synovial cysts; on vaginal examination small hard ovaries were found associated with low blood pressure. In view of the successful results obtained by diathermy on sclerosis and adhesions in general, Laemmer determined to make use of this method, combined with ovarian opotherapy in the form of folliculine and a general tonic treatment, with the result that all three patients made good recoveries.

Pathology.

144. The Rous Chicken Sarcoma.

H. T. DEELMAN (*Ann. de Méd.*, November, 1928, p. 359) criticizes Carrel's recent work on the Rous sarcoma, and reports the result of his own experiments. Three years ago Carrel announced that he could reproduce tumours in the chicken by means of embryonic chicken pulp and a small quantity of arsenic. The tumours were malign, and were, moreover, inoculable with a filtrate devoid of cells. Deelman has been unable to reproduce these results despite the simplicity of Carrel's technique. The Rous sarcoma is described, and the author agrees with those who contend that it is a true tumour and not an inflammatory product. In his experiments Deelman found that the action of the sarcoma virus increases in contact with embryonic cells, the age of the cells having also an influence on the tumour growth, and that the virus is attracted to the living embryonic cells, the containing liquid becoming devoid of it. Applying this to living animals, Deelman surmises that, when the Rous sarcoma necroses, the virus is liberated and is attracted by the environing normal cells, which in their turn become malignant, and by their frequent division cause an intensive growth of the tumour. In the growths produced by Deelman the ordinary characters of the Rous sarcoma are lost, and the tumour resembles rather a medullary cancer. The explanation advanced for this change is that the embryonic cells themselves have assumed proliferative properties. When inoculations are made with the filtrate freed from cells, the tumour produced possesses the classic structure of a Rous sarcoma. When inoculations are made with the tumour tissue itself, a sarcoma of the atypical type is produced, but after the third or fourth inoculation this reverts to the Rous type. Deelman maintains that these results are a further proof that the Rous sarcoma is more complicated than a simple reaction of an inflammatory granuloma type.

145. Pathogenic Leptospira in Water.

A. BESSEMANS and U. THIRY (*C. R. Soc. de Biologie*, (December 21st, 1928, p. 1881) have found in the municipal tap-water at Ghent a leptospira which is pathogenic for the mouse but not for the guinea-pig. The organism was cultivated directly from the water in Vervoort's medium containing 10 per cent. of fresh rabbit serum; pure cultures were not obtained, even after several generations in the laboratory. Morphologically it is said to be slightly larger and longer than *Leptospira icterohaemorrhagiae*. Rabbits injected with cultures produced agglutinins, complement-fixing bodies, and lysins. The lysins were strictly specific, but the other two antibodies acted on a strain of *L. icterohaemorrhagiae*; moreover, a serum prepared against the *icterohaemorrhagiae* strain reacted as well with the water spirochaete as with its homologous strain. The water spirochaete was non-pathogenic to the guinea-pig, but when injected subcutaneously or intraperitoneally into white mice it not infrequently gave rise to an illness ending fatally about the fourteenth to the twenty-ninth day. Quite soon after inoculation these mice showed leptospirae in the blood, and about the tenth day in the urine. About a fortnight after injection the mice appeared ill, cowering in the cage with shaggy coats and dyspnoea. At necropsy their weight was found to be increased, apparently owing to subcutaneous oedema; the lungs were spotted and very hyperaemic, the bladder was filled with albuminous urine containing leptospirae in pure culture, and leptospirae were found in kidney smears, but not in the other organs. Mice injected with the urine or with a kidney suspension developed the disease.

146. The Leucocyte Count in Mumps.

F. JAHN (*Deut. med. Woch.*, November 19th, 1928, p. 1974), in his review of the literature, shows that previous observations on the leucocyte count in mumps have varied considerably. Thus, while Pick, Citron, and Marcowici found normal leucocyte values, Barach reported a high count throughout the disease, and Curschmann, Türk, and Nägeli observed a high count. Studies of the differential count have also led to very different results; whereas Curschmann and Tellez found a lymphocytosis, Marcowici found an increase of the polymorphonuclears and later post-infective eosinophilia, which was also found by Türk and Nägeli from the onset of the disease without any other changes in the leucocyte count. Jahn's observations were made on seven uncomplicated cases of mumps in the acute stage, his results being as follows: leucopenia was never present and normal values were found in two cases, while the rest showed a moderate leucocytosis, which sank to normal again about the fourth week. In five cases there was a lymphocytosis, and in two patients, aged 2 and 17, showed an eosinophilia of 7 and 10 per cent. respectively.

"I find it 'The Finest Mattress Made'"

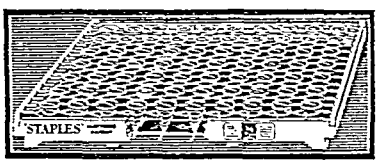
writes *another* invalid lady

"Although no one has asked me to, I must tell you what an excellent thing your 'Staples Bed' is. I am an invalid and stay most of the time in bed. I have had two or three different beds—they went down in the middle after a very short time, so last November I bought one of your beds—it never goes down and is the same now as when I bought it and I am not a fairy. You must really be complimented. After a whole year's use I find it 'The Finest Mattress Made.' You may use my name if you like; I may be a comfort to other invalids." Nov. 5th, 1928.

Mrs. Margaret Shepherd, Wimbledon, S.W.19.

BY APPOINTMENT
Wire Mattress and Bedstead Manufacturers to H.M. THE KING

The writer of this letter was concerned only with the effect of the Staples Mattress upon her sleep. You, as a professional man, will be equally interested in the cause. The highly resilient steel springs of the Staples Mattress support all parts of the body equally, with the spine straight. There is no distortion of internal organs. Muscles are relaxed, nerves refreshed. In every case your best prescription is sleep — sound sleep — on a Staples Mattress.



STAPLES MATTRESS

"The finest mattress made"

A visit to our works showroom at Staples Corner, Cricklewood, is well worth while. The "Commonsense Health" Mattress Booklet and designs of Staples bedsteads are sent post free on application to Dept. 4.

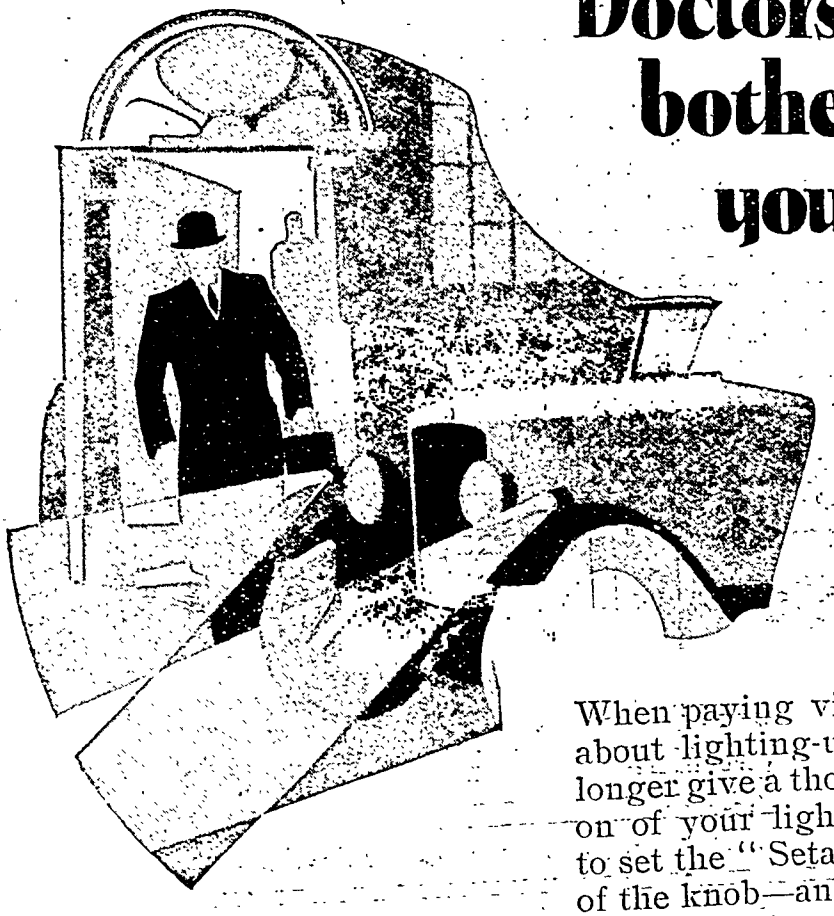
ARE YOUR LAMPS POLICE-PROOF?

Doctors...don't bother about your car-lights



When paying visits to patients, just about lighting-up time, you need no longer give a thought to the switching on of your lights. For you've only to set the "Setalite"—just one twist of the knob—and the lights come on automatically and unfailingly at the right moment.

ORDERS FROM DOCTORS RECEIVE PRIORITY.

The "Setalite" is also indispensable for evening visits to friends' houses, bridge parties, theatres and when shopping, etc. It is a neat little fitment (rather like a speedometer) which you can fix yourself, anywhere on your car, in a minute or two. It is weather-proof and practically unbreakable. It requires no winding and uses no current whatever. It is a universal voltage instrument, and does not in any way interfere with your present lighting system or prevent your switching on by the ordinary switch. It will greatly increase the life of your battery.

Price 45/-, or on deferred payments. If unobtainable from your dealer, write direct to:
SETALITE LTD., 316, REGENT STREET, W.1.

An all round good thing in surgical circles!

We are proud of our Plasters, because we know that better Plasters were never produced. That is why our business is steadily increasing, why the medical profession is more and more relying on us.

Taylors' Zinc Oxide Adhesive Plaster is made from the finest materials obtainable. It keeps a strong grip without fear of slipping and yet removes quickly and cleanly. Non-irritant and thoroughly antiseptic.

Ten-yard spools made in nine widths from a quarter of an inch. Also in rolls seven inches and twelve inches wide.

Taylors' ZINC OXIDE ADHESIVE PLASTER

Inexpensive Antiseptic

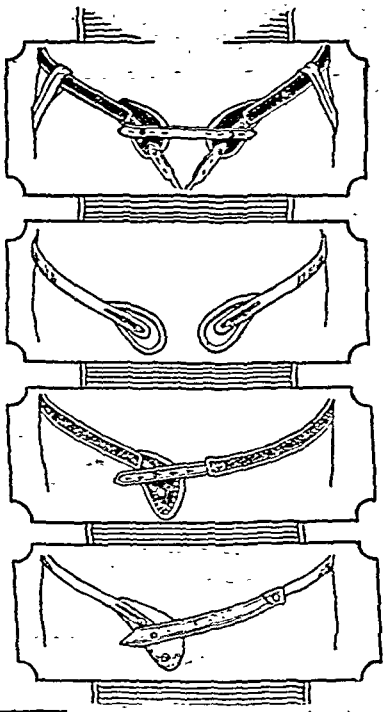
(except in cases of gross carelessness on the Patient's part)
PREVENT
future cases of
SEVERE HERNIA
and greatly alleviate
[illegible]



TREATMENT FOR SEVERE CASES OF HERNIA

Following our last announcement we now raise a point that every medical man will endorse—viz., that (apart from operation) the prevention of the development from simple inguinal to severe scrotal depends upon the efficiency of the support applied.

The Efficient Truss must be subject to numerous modifications. Its spring range must vary from the slightest to the strongest pressure. It must be shaped to fit each case; must be heat-hardened to retain that shape and give pressure on the pads in the correct direction. It must have the pad covering the actual orifice detachable, adjustable, and allowing the minutest alteration in length and fitting.

By our Surgical Service we offer to every medical man means by which properly fitting trusses, with hand-made springs and adjustable heads, can be made to his particular prescription and measurements.

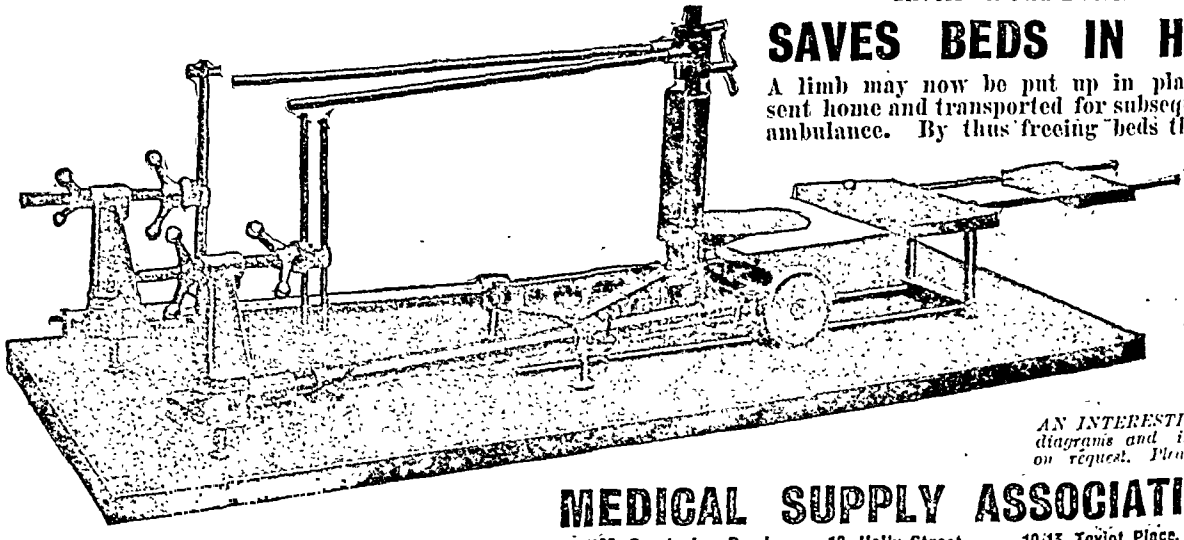
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 11 in. × 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

KROME PLATE
SURGICAL INSTRUMENTS
GIVE LONG LIFE AND RELIABLE SERVICE

DONIGER Krome-Plate Surgical Instruments have proved their definite superiority over ordinary nickle-plate. They are manufactured by highly specialized craftsmen from pore-free high carbon steel. After being polished until they are perfectly smooth and bright, then they are nickel-plated in the usual way, and finally given a heavy plating of chromium. This special process makes Doniger Instruments:

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

Doniger Instruments have been tested over and over again in large hospitals and clinics in America and have always given complete satisfaction. In spite of their many advantages they cost very little more than ordinary nickel-plated instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

SECURE ACCURATE ABDOMINAL SUPPORT & COMFORT FOR YOUR PATIENTS BY RECOMMENDING THE

"ROSE CORSET-BELT"

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Please note new address.

MADAME ROSE, 97, Mortimer St., Regent St., W.1. LANGHAM 1575.

Freshly made Jellies for Invalids

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, unequalled, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from *incipient nervous and mental disorders*, as well as certified patients of *both* sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms *with special nurses, male or female*, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a *Reception* Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. *It is equipped with all the apparatus for the most modern treatment* of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including *Turkish and Russian* baths, the *prolonged immersion* bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a *Dental Surgery, an X-ray Room, an Ultra-violet* Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two *miles from* the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is *trout-fishing in the park*.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 *Northampton*), who can be seen in London *by appointment*.

NATIONAL SUN-RAY AND HEALTH CENTRES LTD.

845/850, SALISBURY HOUSE, LONDON WALL, E.C.2.

The Board of Directors of the above Company desire to make known to the Medical Profession their decision to cease all advertisements to the Lay Public and to conduct their Centres in strict accordance with the recognised principles of the Medical Profession.

Each of their Centres will be under the control of whole-time qualified, registered medical practitioners, assisted by a staff of trained male and female operators.

The Directors desire medical practitioners to realise that they may refer such of their patients as, in their opinion, are likely to benefit by Actino-therapy and other Physio-therapeutic measures, to these Centres with every confidence.

The Medical Officer at each Centre will at all times be pleased to see any local practitioners who may wish to satisfy themselves as to the nature of the provision made for their patients' treatment and comfort.

Interested Practitioners should write to the Head Office for Literature, or to the Ealing Treatment Centre, 23a, The Broadway, Ealing, London, W.5. Telephone: Ealing 2843.

This office being vacant, the States will proceed next month to appoint a Medical Superintendent for the above establishment, who will be required to enter upon his duties about the end of February or beginning of March next.

The appointment is for three years, at a salary of £650 per annum, with house (and garden) in which the person appointed will be required to reside. The Medical Superintendent must devote the whole of his time to the duties of his office. Candidates must be Members or Licentiates of one of the Faculties of Medicine and Surgery of Great Britain or Ireland.

Sealed applications, stating qualifications, with testimonials, to be sent on or before February 9th, addressed to the President of the Committee for the Jersey Mental Hospital, Greffe Office, Jersey.

Greffe Office, Jersey. ERNEST LE SUEUR, Greffier.
January 18th, 1929.

British Red Cross Society's
CLINIC FOR TREATMENT OF RHEUMATIC DISEASES.

A Clinic for the treatment of Rheumatic Diseases will be opened in Park Square, Regent's Park, N.W.1, in the Autumn of the present year.

The British Red Cross Society Committee of the above will shortly proceed to appoint SIX MEMBERS OF THE HONORARY VISITING MEDICAL STAFF, each of whom will be required, when the Clinic is in full working order, to attend twice a week. Application, in the first place by letter only, should be addressed, on or before March 1st, 1929, to the Secretary of the Clinic Committee, British Red Cross Society, 19, Berkeley Street, London, W.1.

Administrative County of Surrey
APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Surrey invite applications from duly qualified medical practitioners holding a Diploma of Public Health for the office of County Medical Officer of Health.

The person appointed will be required to act as Head of the County Medical Services and to perform any additional duties relating to Public Health which may be imposed upon the Council by new legislation.

The remuneration will be a net personal salary of £1,800 per annum.

The appointment is designated an established post under the Local Government and Other Officers Superannuation Act, 1922, and will be held subject to the provisions of that Act, to the Orders for the time being of the Minister of Health, and to the Standing Orders of the Council.

Applications on the prescribed form (which, with a general statement of the conditions and duties of the office, may be obtained from me on receipt of a stamped and addressed envelope) accompanied by copies of not more than three recent testimonials, must be sent in a sealed envelope marked "C.M.O.H.," to reach me at the underwritten address not later than Thursday, February 28th.

Canvassing in favour of a candidate will disqualify.

ARTHUR O. DILLEY AUKLAND,
Clerk of the Council.

County Borough of Smethwick.
SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications from qualified medical men for the position of Senior Assistant Medical Officer of Health.

Salary £550 per annum, with furnished residence for single man at the Isolation Hospital, Holly Lane; including lighting, heating, coal, and laundry. If a married man is appointed the salary will be £700 per annum, without board and residence.

His duties will be to act as Medical Officer at the Isolation Hospital, to work at the Tuberculosis Dispensary and School Clinics on certain days, and to carry out a certain amount of School Medical Inspection.

Applicants must be registered medical practitioners, and should possess the Diploma of Public Health.

The officer appointed will also be required to assist the Medical Officer of Health in his other duties from time to time as directed, and will work under the general supervision of the Medical Officer of Health.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, to whom applications, endorsed "Assistant Medical Officer of Health," accompanied by copies of three recent testimonials, must be delivered not later than February 14th.

Canvassing, directly or indirectly, will disqualify.

Council House, Smethwick. FRANK CHAPMAN, Town Clerk.
January 29th, 1929.

The Board of Control (Lunacy AND MENTAL DEFICIENCY) invite applications for the post of MEDICAL OFFICER (male), at RAMPTON STATE INSTITUTION FOR MENTAL DEFECTIVES, near RETFORD. The salary will be £400, rising by annual increments of £20 to £600. Bonus, which varies with the cost of living, is also allowed. For bonus on salary of £400 is £136 10s. The emoluments are free furnished quarters, coal, laundry. Board and service will be provided on payment of the actual cost.

Candidates must be registered medical practitioners, unmarried or widowed, and must be natural-born British subjects and the sons of natural-born British subjects. The appointment will be pensionable under Civil Service Superannuation Acts.

Forms of application, with further particulars, can be obtained from the Secretary, Board of Control, Caxton House, West Tower, Westminster, London, S.W.1, and must be completed and returned to him not later than March 9th.

Asylum Service.—Junior ASSISTANT MEDICAL OFFICER wanted, commencing £275, with board, lodging, and laundry. Every encouragement given for research work. Applications should be addressed to Dr. J. H. MACFARLANE, Superintendent, Hawkhead Asylum, Paisley, Glasgow, S.W.2.

Cardiff Union.

ASSISTANT MEDICAL OFFICER.

The Guardians of the Cardiff Union require a Third Male Assistant Resident Medical Officer for the CITY LODGE INSTITUTION, who must devote the whole of his time to the duties, reside in the Institution, and (subject to the orders of the Guardians) act under the direction of the Medical Officer.

The qualifications, conditions, and duties of the appointment, which will be for six months, but renewable if the Guardians see fit, are prescribed by general orders of the Ministry of Health, and are further defined in rules adopted by the Guardians, a copy of which (and any other information desired) may be obtained from me. One duty will be to give such lectures to the Nurses as may be required.

The salary will be at the rate of £100 a year, with rations, apartments, attendance, and washing, subject to the provisions of the Poor Law Officers Superannuation Act, 1896, for which the present value of emoluments is fixed at £154 10s. a year.

Assistant Medical Officers are liable to be called upon by Justices to examine and certify alleged Lunatics, for which fees are payable.

Applications, on forms to be obtained from me, must reach me by 10 a.m. Thursday, February 21st.

Direct and indirect canvassing is prohibited.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Introduction of six months if required.
2. LONDON, S.E. (CROYDON AREA).—Old-established rapidly increasing middle-class PRACTICE. Income for immediate past year over £1,300, including panel of 700. Surgery fees 2/6 to 5/-. Visits 3/6 to 10/6. Thirty midwifery cases yearly from 3 to 10 guineas. Very commodious house on lease, with 11 years to run, rent £70. Premium £2,000.
3. WITHIN ONE MILE OF MARBLE ARCH.—PARTNERSHIP.—A Half Share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,750. Premium £4,000. Must be Scotch or English.
4. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
5. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
6. SOUTH-EAST OF ENGLAND.—COAST TOWN.—Small but increasing PRACTICE, at present producing about £500 per annum, with good scope. Panel of 420 Suitable house available. Rent £52 p.a. Premium £500, part down, and balance by instalments.
7. PARTNERHIP.—The Third share of a very old-established mixed-class Practice, in a pleasant London suburb, is for disposal owing to the retirement (through ill health) of the Junior partner. Held 24 years by remaining. Cash receipts average about £2,700 p.a., including appts. producing £340 and panel of 1,000. Visits 3/6 to 21/-. Good house available, with ample accommodation. Rent £85 on lease. Premium 2 years' purchase. Excellent scope.
8. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium £500.
9. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
10. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
11. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE Income for the immediate past year about £2,500, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6. Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £3,500
12. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly. Moderate expenses Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Price for freehold £1,500. Premium £4,500.
13. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery 2 gns. upwards. Good house in excellent repair, with 2 reception 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300. Premium £1,400.
14. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1¼ acres, and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
15. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
16. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200 Premium 1½ years' purchase.
17. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs' pur.
18. SUNDERLAND. — DEATH VACANCY. — Old-established non panel PRACTICE, averaging for last three years £1,030 p.a. Fees 3/6 to 10/6. Midwifery 3 to 7 guineas Good corner house, on main road, with 4 reception and 4 bedrooms, etc. Will be let or sold. Good scope for panel if desired. Excellent Locum in charge. Offers invited.
19. WILTSHIRE.—Unopposed old-estab. Country PRACTICE, situated in very pretty district and averaging £700 p.a., including Union appt. £70, and panel producing £450. Nearest opposition 3½ miles Railway station 1 mile. House stands in own grounds of 1½ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,500, all of which could remain on mortgage if wished. Premium £1,050.
20. NORTHUMBERLAND.—Small middle-class PRACTICE, offering scope for increase. Income for past three years has averaged over £450 p.a. Panel (which has been discouraged) numbers about 70. Fees 2/6 to 21/-. Midwifery from 3 gns. Convenient eight-roomed house, in good position, with large garden. Rent £50 p.a. Premium £450

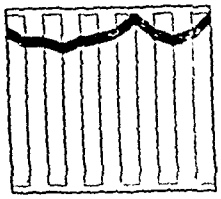
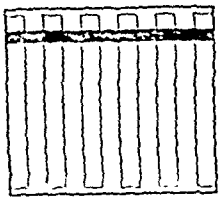
No pulse irregularity after drinking this Coffee

There is no danger to the heart from caffein, because - -



IRREGULAR PULSE — AFTER DRINKING ORDINARY COFFEE



REGULAR PULSE — AFTER DRINKING H. A. G. COFFEE

H.A.G. COFFEE

is 97% decaffeinized

Ordinary coffee contains from 1% to 2% of caffein. It is largely because of this drug that coffee causes irregular palpitation (see chart above), increased blood pressure, irritation of the cardio-inhibitory vagus centre, and other conditions.

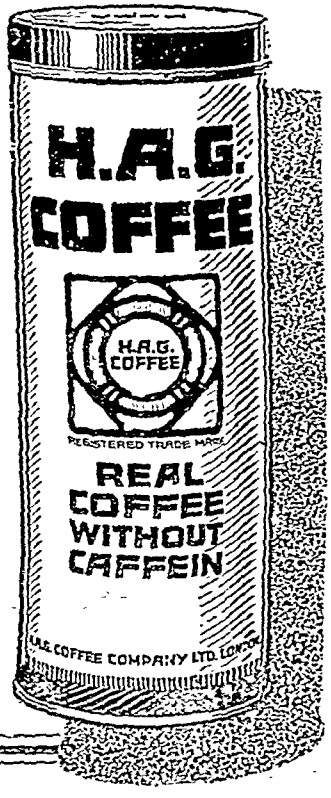
Yet, there is a coffee that patients can drink without danger from caffein. It is a delicious blend of fine coffees from which 97% of the caffein has been removed. H.A.G. COFFEE does not affect the pulse—as can be seen from the diagram at the right.

A REAL COFFEE WITH A REAL FLAVOUR

H.A.G. COFFEE is REAL coffee — not a substitute in any sense of the word. It is a choice blend of the finest Central American and South American coffees on the market. By extracting the caffein BEFORE ROASTING, all the original rich, delicious flavour and aroma has been retained

Patients who balk at substitutes will welcome the change to H.A.G. COFFEE, for it is superior to most ordinary coffees. In nearly every case they will find it more delicious than their customary blend.

Price per large "Household Size" tin, in the Bean or Ground - - 3/2



A free sample, together with a very interesting booklet "Contra Indications of Caffein" by Prof. Dr. Mendelsohn, Berlin, will be sent to any member of the medical profession upon application.

HAND PLOUGH USED BY THE YAMATO PIONEERS, WHO, BY SETTLING DOWN TO AGRICULTURAL PURSUITS, MADE POSSIBLE JAPAN'S FURTHER PROGRESS TOWARDS CIVILISATION.—Desire to possess the alluvial plains of Japan would seem to have been the incentive which drew the conquerors from the mainland of Asia. In stirring up his companions to accompany him upon an invading expedition, Jimmu the legendary founder of the Empire, referred to the islands as "the land of fair rice-ears of the fertile reed-plain." The Yamato set themselves, with great energy, to reclaim land for rice cultivation, and some of their most important laws were directed against crimes which damaged the crops of rice. Rice was then, as now, the staple Japanese food, and the national beverage, saké, has been brewed from it from the earliest times. The cultivation of rice became the chief industry of the country and, since the preparation of the fields is an extremely arduous and complicated undertaking, much co-ordination of labour and rational organisation were involved. An ancient record gives a vivid insight into this activity in the year A.D. 6: "In this year the various provinces were commanded extensively to excavate ponds and channels to the number of eight hundred and more. Much attention was thus paid to husbandry. Therefore, the people enjoyed abundance and the Empire was at peace."

—BRITISH JOURNAL OF SURGERY.

With 6 Col. Plates and other Illus. Cr. 8vo. 7s. 6d. net; postage 5d.

THE PATHOLOGY, DIAGNOSIS, AND TREATMENT OF NEOPLASMS ORIGINATING IN THE WALLS OF THE URINARY BLADDER. A Monograph based on the Buckston Browne Prize Essay for 1927.

"Gives a well-rounded account of an interesting subject."
—THE LANCET.

LONDON: H. K. LEWIS & Co. Ltd., 136, GOWER STREET, W.C.1.

Telegrams: PUBLICAVIT, EUSROAD, LONDON. Telephone: MUSEUM 7756 (3 lines).

SECOND IMPRESSION. Cr. 8vo. 168 pp. 7s. 6d. net; postage 4d.

THE ELEMENTS OF
MEDICAL TREATMENT

By ROBERT HUTCHISON, M.D., F.R.C.P.,
Physician to the London Hospital.

"A model of brevity, clearness, and sound judgement."
—*British Medical Journal.*

ALSO BY THE SAME AUTHOR.
Crown 8vo. 2s. 6d. net; postage 2d.

SOME PRINCIPLES OF
DIAGNOSIS. PROGNOSIS AND TREATMENT

"There can seldom have been more interesting and shrewdly worded advice than that closely packed in these pages."
—*British Medical Journal.*

Large 8vo. 228 pages, with 251 Illustrations, some of which are in Colour. 21s. net; postage 6d.

DEMONSTRATIONS OF
PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng.,
Surgeon, Dudley Road Hospital, Birmingham.

The Illustrations form a prominent feature of the volume, and much care has been taken to render them as accurately as possible.

"It was time a book of this nature was available in English, and the author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which are informative."—*Lancet.*

"We have nothing but praise for this book."—*Edin. Med. Journ.*

Bristol: JOHN WRIGHT & SONS Ltd. [Catalogue free.] London: SIMPKIN MARSHALL Ltd.

THIRD EDITION. JUST PUBLISHED.

DISEASES OF THE LIVER, GALL-BLADDER, AND BILE-DUCTS

By Sir HUMPHRY ROLLESTON, Bart., M.D., Regius Professor of Physic in the University of Cambridge; and JOHN WILLIAM McNEE, D.S.O., M.D., D.Sc., Associate Physician to University College Hospital.

MACMILLAN & CO., LTD., LONDON, W.C.2.

THIRD EDITION (3rd IMPRESSION). Crown 8vo. 4s. net, postage 2d.

THE INJECTION TREATMENT OF VARICOSE VEINS

By A. H. DOUTHWAITE, M.D., M.R.C.P.Lond.

"The ambulant treatment of varicose veins and haemorrhoids has recently attracted great interest among all grades of our profession, and Dr Douthwaite has summed up our present knowledge of the treatment in a most readable and clear manner. . . . We can commend the book most heartily to our readers."—GLASGOW MEDICAL JOURNAL.

LONDON: H. K. LEWIS & CO. Ltd., 136, GOWER STREET, W.C.1.

CASSELL AND COMPANY, LTD.

NOW READY.

NINTH EDITION.

MANSON'S TROPICAL DISEASES

Edited by PHILIP H. MANSON-BAHR,

D.S.O., M.A., M.D., D.T.M. & H.Cantab., F.R.C.P.Lond.

The Ninth Edition of this Manual brings together the new knowledge acquired by various workers in the field of tropical medicine. A notable feature is the extension and amplification of methods of treatment which are becoming more and more stabilized. Every chapter has been drastically revised, and many parts of the book have been rewritten.

The sections devoted to protozoology and laboratory technique have also been thoroughly revised, and the illustrations have been reinforced by the addition of nine new plates and some thirty new text-figures.

Demy 8vo, 942 pages. With 23 Colour and 12 Half-Tone Plates, 401 Illustrations in the Text, 6 Maps and 34 Charts. **31s. 6d.** net.

NOW READY.

NEW WORK.

TROPICAL NURSING

By A. L. GREGG, M.A., M.D., M.Ch., D.T.M. & H.Lond.

With a Foreword by the **Hon. Sir ARTHUR STANLEY**, G.B.E., C.B., M.V.O.

TROPICAL NURSING has been written to meet the requirements of nurses working in the tropics. The nursing of the principal tropical diseases is lucidly dealt with, and there is also much practical advice on personal hygiene, food, drink, clothes and kit, etc. Other sections are devoted to nursing technique and the care of the eyes.

Foolscap 8vo, 212 pages. With Illustration in the Text. **6s.** net.

NOW READY.

SEVENTH EDITION.

ELEMENTS OF SURGICAL DIAGNOSIS

By Sir ALFRED PEARCE GOULD.

Revised by ERIC PEARCE GOULD, M.D., M.Ch.Oxon., F.R.C.S.Eng.

This Volume has been subjected to a careful revision and is now once more abreast of the knowledge upon which the diagnosis of surgical conditions is based.

The increasing rôle played by X-rays in surgical diagnosis is signalized by the addition of several new radiographic plates and appropriate recognition in the text. Cholecystography, and the use of Lipiodol with X-rays, have been introduced into the new edition.

Foolscap 8vo, 744 pages. With 26 Radiographic Plates. **12s. 6d.** net.

NEW WORK.

THE ESSENTIALS OF MEDICAL DIAGNOSIS

A Manual for Students and Practitioners

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P.Lond.,

and A. E. GOW, M.D., F.R.C.P.Lond.

This Manual consists of concise descriptions of the methods of investigating cases of disease in the manner actually carried out in practice. The authors' plan is to work from the patient and his complaint to the disease from which he suffers, and not in the opposite direction.

"*Well written and thoroughly practical.*"—BRITISH MEDICAL JOURNAL.

"*A successful attempt . . . to relay the foundation-stones of the art of diagnosis.*"—LANCET.

Crown 8vo, 702 pages. With 8 Colour and 11 Black-and-White Plates, and Figures and Charts in the Text. **16s.** net.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

J. & A. CHURCHILL

NOW READY. With 13 Coloured Plates and 49 Text-figures. 15s., postage 9d.

RADIUM TREATMENT OF CANCER

By STANFORD CADE, F.R.C.S.,
Assistant Surgeon, Joint Lecturer on Surgery and Teacher of Practical Surgery, Westminster Hospital.

NOW READY. Third Edition. 10s. 6d., postage 6d.

MALAY POISONS AND CHARM CURES

By JOHN D. GIMLETTE, M.R.C.S., L.R.C.P., late Residency Surgeon, Kalantan, Unfederated Malay States. With Foreword by Sir W. H. WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P., Medical Adviser to the Home Office.

SOME FAMOUS MEDICAL TRIALS

By L. A. PARRY, M.D., F.R.C.S. 10s. 6d., postage 6d.

CONTENTS:—Murder—Treason—Forgery—Abortion—Poisoning of Wife and Mother-in-Law—Blackmail—Doctor murders Doctor—Doctor libels Doctor—Bigamy—Bodies slain, and bodies stolen for Dissection—Ears cut off for Libel—Dismissal from the Navy—Dr. and Mrs. Crippen and Miss Le Neve—Prosecution of Dr. Hadwen.

270 Illustrations, 4 Coloured Plates. 18s., postage 9d.

THE QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS

By J. B. BANISTER, M.D., C. S. LANE-ROBERTS, M.S., A. W. BOURNE, M.B., L. G. PHILLIPS, M.S., T. B. DAVIES, M.D., L. C. RIVETT, M.C., F.R.C.S.
(Members of the Staff of the Hospital).

SECOND EDITION. 219 Illustrations, many in Colour. 28s. net, postage 9d.

FRAZER'S ANATOMY OF THE HUMAN SKELETON

"The underlying principle of the book is sound and commendable . . . the author has succeeded admirably in his aim."—BRIT. MED. JOUR.

By J. A. CROWTHER, Sc.D., F.Inst.P., Professor of Physics, University College, Reading.

OBTAINABLE FROM ALL DEALERS, OR FROM THE BRITISH DISTRIBUTORS:

HAWKSLEY & SONS, Ltd., 83, Wigmore St., London, W.1

THE BRITISH MEDICAL PROTECTION SOCIETY

are constantly striving to help the Medical Profession to get prompt payment of accounts. Owing to the amazing increase of road accidents, we were moved to send the following letter to one of the National Daily Newspapers, which was published in their columns on January 28th:

To the Editor.

SIR,—The leading article on Friday on this subject naturally interested me, because I hear and read both sides of this interesting subject.

When an accident occurs both parties generally blame one another and they both feel that if they pay the doctor they will be admitting liability. I suggest one of the following alternatives should be adopted if the motorists and the insurance companies wish to save human lives, time, and money.

(a) Where the parties cannot or will not agree as to the cause they should jointly contribute half each to pay the doctor's fee and both claim from their insurance company.

(b) Where only one driver is concerned he should pay the doctor on the condition that a receipt is given for services rendered, not because liability is admitted (marked on receipt); then claim against the insurance company

I think the insurance companies might help by stating that in the event of the compulsory attendance of a doctor (by the roadside) they will pay their share of the fee. It is in their own interest, because immediate attention would in a great many cases save life or long attendance.

Some clause to this effect would give doctors confidence in the motorist which they have now lost.

N. RUTHERFORD WATSON,
British Medical Protection Society,
4, Margaret Street, Cavendish Square,
London, W.1.

If you are in any difficulty in respect of services rendered in road accidents, or otherwise, we should be pleased to place our experience at your disposal.

A prompt, painless eliminant and anti-acid.

One or two drachms of Sal Hepatica induces quick, painless and complete evacuation, which eliminates all toxic substances, reduces the blood pressure and renders the blood and urine alkaline. ¶ The toxic amino-acids present in the system which result in diabetes, rheumatism, gout, sciatica, lumbago, neuritis and all other disorders associated with acidosis, can be eliminated daily by the exhibition of Sal Hepatica. ¶ Sal Hepatica is non-habit-forming.

Sal Hepatica

the proved medicinal saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession, on application to

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. Nujol readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis, frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of constipation.

"A SENSE OF INCREASED FITNESS"

"I have now been prescribing Bemax in my practice for well over a year, and I think it only right to let you know that I am very well satisfied with the results obtained. There is no doubt, in my opinion, that the regular addition of Bemax to the diet (even of apparently healthy individuals) leads to a sense of increased fitness and better general health. I have proved this by personal experience as well as observation on and statements from others. As regards pathological cases, I have found it particularly useful in Dyspepsia and Chronic Constipation."

M.B., Ch.B., D.P.H.

Bemax is now established as the B vitamin food. Over 25,000 members of the medical profession are taking Bemax themselves or prescribing it for their patients, with excellent results. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxaemia, Debility, Neurasthenia, Rheumatism, Gastric disturbances and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full size tin will be sent you on receipt of your professional card.

Influenza and Capillary Tone

Another influenza epidemic finds us still without a specific preventive or a specific remedy. Fortunately, both the incidence and the course of the disease can be favourably modified by the observance of such rules as medical experience teaches.

It is essential to maintain vigorous metabolism and healthy capillary tone, whilst avoiding undue cold and damp. Adequate stimulation of the sensory nerve-fibrils of the skin, also, is of supreme importance in keeping the body's resisting power at its highest, and in increasing its recovery-capacity. For these purposes, THERMOGENE has been found by many medical men and their patients to be convenient, cleanly and effective.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE
MEDICATED WADDING

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice.
The Thermogene Co., Ltd., Queen's Road, Haywards Heath, Sussex.

INSULIN "A.B."

TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

Supplied in two strengths:

20 units per c.c.

The following figures are significant as definitely establishing the bacteriological efficacy of Lysolats

Professor Huynen of the State Veterinary University of Brussels recently discovered that a 1% solution of Lysolats (solid form of lysol) in water arrested the developments of bacterial growth in two seconds.

A 1% solution of Lysolats was tried on the following organisms:—

B. Coli	was killed	in 40	seconds.
B. Bang	„	„	„
B. Pneumococci	„	„	„
B. Typhosus	„	„	„
B. Staphylococci	„	50	„
B. Pyocyaneus	„	„	„

These facts should be of special interest to House Surgeons and Physicians, Hospital Dispensers, Medical Officers of Health, etc. While the cresylic acid content of saponified tarry preparations is of some importance, it will be agreed that germicidal efficiency is the vital factor in the choice of an antiseptic and disinfectant. Lysolats are an antiseptic and disinfectant fulfilling the recognized standards, but with a greater germicidal power than any other known to science.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Lysolats

PATENT 115667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

ALOCOL

Colloidal Hydroxide of Aluminium.

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy, because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralizing it. "Alocol" thus prevents reabsorption, accumulation, and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing, and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasia, gastrolcosis, pyloric and duodenal ulcers, infective enteritis, etc.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

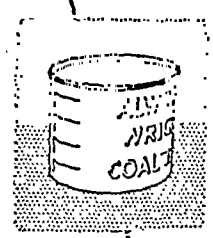
WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

"LYSOL"—Your patients must always qualify the word.

To ask merely for "Lysol" is dangerous, for they may be given an inferior Lysol that will actually do far more harm than good. Tell them, for their own safety, to insist on Wright's Lysol. It gives sure results—always. It is perfectly pure, non-caustic, and causes no irritation. British owned and made under the strict Rideal-Walker control test by the makers of the world-renowned Wright's Coal Tar Soap—Producers of Disinfectants for over sixty years.

Tell your patients to say "Wright's" before saying "Lysol." That way lies certain safety and protection.



A handy graduated measure is provided with every bottle.

Streets 68

"... All of which made rapid improvement"

MANY letters are received from members of the Medical Profession testifying to the excellent restorative and stimulative properties of "New-Promonta." The following is typical:

19.11.28.

"I have had the opportunity of testing your product out in 3 cases, all of which made rapid improvement:

"*Case 1.*—Adult male, suffering from neurasthenia of two years' duration. He had drifted from one doctor to another during that period, receiving various treatments. After the first few days' treatment with "New-Promonta," he stated that he felt 'an entirely new man,' and he continues to improve.

"*Case 2.*—Adolescent youth, suffering from languor, anorexia, and anaemia. Since he has taken small morning and evening doses of your product he has improved steadily.

"*Case 3.*—Medical practitioner, suffering from the mental and physical strain of the present influenzal epidemic. He states: 'Every dose of "New-Promonta" puts new life into me.'

"Personally I consider you have produced an excellent nerve tonic and will continue to prescribe it."

(Signed)..... M.B., Ch.B.

The most important feature of "New-Promonta" is the retention, in an absolutely unchanged form, of Lipoids, Phosphatides, and Vitamins in the exact quantities and proportions necessary to induce active cell metabolism. In all of the following, therefore, "New-Promonta" forms an exceedingly effective treatment.

(1) All forms of Neurasthenia. (2) Insomnia. (3) Various types of Anæmia. (4) After effects of Influenza. (5) Conditions of Functional Insufficiency. (6) In Illness and in Convalescence.

"New-Promonta" is obtainable from high-class chemists in metal boxes of 54 tablets at 3/6 a box. Each box contains a small aluminium tube for the vest pocket, large enough to hold a day's supply. In powder form "New-Promonta" is sold in tins of two sizes—¼-lb. size at 3/-, and ½-lb. size at 5/6.

FREE SAMPLES for clinical trials are at the disposal of the Medical Profession.

Solving a Food Problem

HOVIS

Most nourishing Bread

After all the discussions as to the relative values of white, wholemeal, and various brown breads, it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as HOVIS, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time, impairs health, and, with children, prevents perfect development.

HOVIS, even in small quantities, provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

HOVIS Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "brownness" of bread is not a measure of its vitamin content. HOVIS does not contain bran, and is easily digestible.

Note the following figures showing the Vitamin B content of milling products and yeast in 100 g. dried bread:

White Bread	200
Wholemeal Bread	1,450
HOVIS Bread	2,600

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals HOVIS.

Wholesale and Export Druggists and Manufacturing Chemists.

Specially indicated in
NEPHRITIS—URÆMIA
ECLAMPSIA—ALBUMINURIA

and allied conditions

Prompt and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea. Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated.

They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregna cy.

The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

Pioneers in Endocrine Therapy

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND ENDOCRINE INSUFFICIENCY

A WRITER in THE LANCET has directed attention to an apparent connection between alimentary toxæmia and endocrine insufficiency, particularly of the thyroid gland. Many cases of "ill-health," neurasthenia and others, were benefited by the administration of thyroid extract.

He goes on to remark that there seems to be a close connection between endocrine insufficiency and poisoning from intestinal absorption, and notes the beneficial results obtained by the use of intestinal antiseptics in addition in these cases.

He seems to be unaware that the best of all intestinal antiseptics is Kerol. In endocrine insufficiency, therefore, use Kerol in addition to other measures.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

INFLUENZA

The nasal and oral cavities are the usual route of infection. Mistol applied with a Mistol dropper in the nose is an ideal preventive. Being an oily preparation Mistol diffuses and spreads itself in a thin film over all parts of the mucous membranes of the nose and throat. It clings tenaciously to mucous membranes, and is not easily washed away by the natural secretions. Thus it affords relief in all inflamed and irritated conditions, and assists in warding off infection.

Sold in original sealed cartons containing a—

"VITAMALT"
Reg.

Rich in essential Vitamins A, B, C, & D

VITAMALT is a scientific preparation containing the finest Malt Extract of high diastatic value, with selected ingredients rich in Vitamins. It is a well-balanced food that ensures an adequate supply of Vitamins A, B, C, and D, and corrects all ailments arising from deficiency of these vital factors. This unique combination of Vitamins has been skilfully blended to make a preparation which is easily assimilated and very pleasant to take. The regular use of Vitamalt can be relied upon to provide the necessary Vitamins, A, B, C, and D, which will help to build a healthy body with sound nerves, firm bones, good teeth, and rich blood. Vitamalt is suitable for children and adults of all ages.

PRICE 1/9 and 3/- per jar.

Obtainable from all branches of Boots

CALCIUM THERAPY

Calcium, essential to life, appears to diminish the permeability of the blood and lymph vessels and cell membranes. Its therapeutic application has increased considerably of recent years. Its administration raises the Calcium content of the blood and thereby tends to reduce undesirable secretions such as occur in certain inflammatory conditions of the skin and mucous membranes. Hence its value in retarding pleural effusion and oedema of the lungs, and for the relief of chilblains and erythematous conditions generally. Its role in the regulation of bony structure is also recognised.

EVANS'
COLLOIDAL CALCIUM

This is a stable and efficiently protected colloidal solution of the oleate and contains 0.05 per cent. of Calcium. Its use ensures rapid assimilation and most effective results with almost painless hypodermic administration. It is also supplied for oral administration.

EVANS' PARATHYROID AND CALCIUM LACTATE TABLETS

Combined with parathyroid one gets stimulation of glandular function with an increase of the therapeutic action of Calcium.

These products are scientifically prepared at
EVANS' BIOLOGICAL INSTITUTE, RUNCORN.

AETHER PURISS. B.D.H.

The advantages of employing only the purest ether for anæsthetic purposes are now recognised by anæsthetists generally and indeed by the whole medical profession.

The British Drug Houses Limited, realizing the outstanding importance of purity, several years ago conducted an investigation and discovered new methods for detecting the impurities occurring in anæsthetic ether. Also, they detected impurities hitherto unrecognised, and, finally, prepared an ether in a state of purity heretofore never offered to anæsthetists.

Aether Puriss. B.D.H. is unique; in fact, to use the phrase of a well-known anæsthetist, Aether Puriss. B.D.H. is

". . . in a class by itself."

In order to prepare ether up to the standard of purity for Aether Puriss. B.D.H. laid down in the B.D.H. laboratories it was necessary to use pure rectified spirit to which no methylating agent had been added. Permission to do this was granted by H.M. Commissioners of Customs and Excise to The British Drug Houses Limited some three years ago, and throughout its production on a commercial scale Aether Puriss. B.D.H. has been made from pure rectified duty-free spirit and not from methylated spirit.

Aether Puriss. B.D.H. is not only made pure, but it is kept pure; it is packed in small light-proof bottles to ensure its arrival in the operating theatre in its original condition, thus preserving its freedom from all traces of toxic impurities.

RELIEF!

....from the moment it is applied!

Relief, too, for the busy nurse, who knows from experience that ANTIPHLOGISTINE applied warm and thick can be depended upon to supply and maintain a uniform degree of moist heat during her entire off-duty period.

By virtue of the synergistic combination of its ingredients the osmotic action of Antiphlogistine begins promptly, activating the superficial circulation, decongesting and allaying the painful processes without irritation, and inducing natural and restful sleep.

Prescribed by the Medical Profession the world over for more than a quarter of a century in preference to fomentations and messy flaxseed poultices because its efficacy in the treatment of inflammations of both superficial and deep-seated structures has never been questioned.

Antiphlogistine

A proven adjuvant in the treatment of Pneumonia.

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

"RYVITA" CRISPBREAD"

'BYNIN' AMARA

(TRADE MARK)

A Powerful Tonic and Hæmatinic

'Bynin' Amara is of special value in influenzal conditions and in the marked asthenia and nervous depression which are prominent features of the post-influenzal state. A course of 'Bynin' Amara whenever there is any indication of lowered resistance is a valuable safeguard against infection.

It has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

In bottles at 3/6, 6/6 and 12/-

Further particulars and free sample will be sent on request

COMPOSITION

Quinine Phosphate	1½ gr.
Iron Phosphate	2 "
Nux Vomica Alkaloids equal to Strychnine ⅙	"
'Bynin' Liquid Malt	1 oz.

Allen & Hanburys Ltd.

Reminders and Suggestions

For the
Treatment of
INFLUENZA, PNEUMONIA, Etc.

CRYOGENINE (Lumière)

A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy.

Powder and Tablets: Dose—From 0.50 to 2.50 gm. daily as required.

ORARGOL

An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis, and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

Literature and Samples on request from

THE ANGLO-FRENCH DRUG CO., Ltd.,
238a, Gray's Inn Road, LONDON, W.C.1.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN
CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

The Huxley Lecture

ON

THE NATURE OF DISEASE.

DELIVERED AT THE UNIVERSITY OF BIRMINGHAM ON FEBRUARY 12TH,

BY

SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D., HON.D.Sc., D.C.L., LL.D., REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

HEALTH is the state of body and mind resulting from the successful adaptation of the living organism to external and internal factors. Dis-ease (want of ease), which is a departure from this condition of equilibrium or a want of harmony, has been often defined, but the definitions have not given universal satisfaction, and, as Mercier pointed out, it is noteworthy that the fundamental concepts of other callings, such as the law, engineering, finance, and war, are also hard to define, and that this process of specification, so to speak, is not arrived at until late in their history, though their practical efficiency has not been thereby affected. Definitions are a weariness of the flesh, but it may be well to quote one out of many—that formulated by the late J. G. Adami in 1910—as it contrasts with that of health and gives a good indication of the potential variability in the reaction we call disease; it runs as follows, "Disease is a process or succession of disturbances induced by any agent which disturbs the normal activities of the organism as a whole or of its constituent parts." Into another definition—that "disease is a failure of adaptation both to conditions without the organism and within" (W. A. White)—may perhaps be read two additional points: first, that the responsible cause may be inside the body, quite independent of any extraneous factor—for example, some congenital structural defect or a functional aberration, such as "the inborn errors of metabolism" or "chemical malformations" described by Archibald Garrod: and secondly, that in the process of adaptation not only may the normal reserve power of the living body be called upon, but that in comparatively slowly developing morbid changes, such as valvular disease of the heart and narrowing of canals such as the intestine, compensatory or adaptive processes, secondary to, but keeping pace (at any rate for a time) with the morbid change, may bring about such an adjustment that there is absolute freedom from symptoms. Thus destruction of one kidney may be compensated by hypertrophy of the other, and destruction of a portion of the liver by regeneration in the remainder. Symptoms, and disease in the sense to be explained directly, will only occur when these compensatory muscular and glandular hypertrophies fail; the hitherto latent morbid change then gives rise to functional disorder—that is, symptoms. This "margin of safety" or compensatory mechanism must be borne in mind as a difficulty in attaining the desired knowledge from the study, so much insisted upon by the late James Mackenzie, of the earliest departures from health; for by the time symptoms appear the morbid changes may be well established, and the manifestations might then be wrongly regarded as functional changes leading up to, and responsible for, the structural alterations. The mechanisms which compensate or restore damaged tissues or impaired functions, though for a varying time eminently successful, tend eventually to fail and then to become harmful: thus, according to Thoma's histo-mechanical conception of arterio-sclerosis, there is in the first place a local thickening of the inner coat of the artery to obviate a bulging at a spot where it would occur as the result of degeneration of the muscular middle coat; in course of time, however, the thickened area in the intima also degenerates, and what was a compensatory process becomes a morbid lesion. Further, the compensatory and defensive powers of the body may from the outset be ineffective—for example, when inflammation, defined as "the local attempt at repair of actual or referred injury" (Adami, 1896), rapidly produces suppuration; this idea is also expressed with regard to malignant disease in George Newman and J. A. Murray's dictum that "cancer may be considered as an aberration of the process of repair."

WHAT IS A DISEASE?

To consider now in rather more detail the question, What is a disease? Primitive man is superstitious and has always regarded disease and accident as due to the action of an offended or malicious deity, of the dead, or to the machinations of an enemy, and from the last belief was derived the idea of magic and witchcraft. Disease became regarded as a definite invasion of the body, as by demoniac possession or by a more material substance, which must be allowed an exit, as by the trephining in Neolithic times, or expelled, in order to obtain a cure. This notion that the cause of disease was the presence in the body of a foreign spirit or of some concrete substance with an extra-corporeal existence or phase obviously expresses, though in less scientific terms, the more modern knowledge of parasitic and bacterial infection, and so far may be regarded as prophetically rational. To discover the cause of the disease is the aim of diagnosis, and so keen is the appreciation of this important principle that there is still a tendency to regard the cause as synonymous with its results. A not unnatural outcome of the belief that disease was a disorder with an objective reality and due to some harmful substance in the patient's body was the materialization of diseases on the lines of botanical and zoological classifications, and to arrange them in genera and species after the successful plan initiated by Linnæus. For this view Thomas Sydenham (1624–1689)—the British Hippocrates—was in part responsible. The rival *nosologies* of Felix Plater (1650), de Sauvages (1763), Vogel (1772), MacBride (1772), William Cullen (1785), Thomas Young (1813), John Mason Good (1817), and others elaborated this conception. Even now diseases are spoken of, though perhaps not seriously so visualized, as quite definite things: and it may be asked, What practical difference does it make if they are? A partial answer is that this would logically justify a rule-of-thumb practice of treating the disease rather than the sufferer. In this age of mass production and machine-made standardization, when, for example, motor cars are so alike that their disorders are of a stereotyped character, it is particularly important to insist on the obvious—namely, that human beings are made, not from one mould, but individually, differing widely in their make-up and power of response. In illness we all desire to be treated as a special problem, not as one of a crowd of Robots, and accordingly trust our medical attendants not only for their technical knowledge but also for their ability of applying it to our particular needs. Every illness is the reaction of the body and mind of the patient to some factor which in its turn may be simple or complicated; the reactions of living matter are far from constant, and those of man become more complex as he moves from childhood and the simple life of the country to maturity and the whirlpools of modern civilization. Thus a startling or offensive announcement may leave one man untouched because he is deaf; another, phlegmatic or a philosopher, may receive it in silence; whereas in a third an emotional explosion follows. This variation in the response is most dramatically seen in idiosyncrasies, such as asthma and hay fever, as the result of inhalation of horse emanations or of pollens, or of abdominal and cutaneous symptoms, as the result of eating a few specks of parsley—an example of which in four generations of a family has just been brought to my notice. As in other matters, the problem, much discussed more than sixty years ago by Handfield Jones, Wilks, and W. Broadbent, whether to treat the disease by routine methods or the patient, is best solved by a compromise of judicious combination; for to treat the man without any reference to his malady—for example, if he is weak and his strength failing to be content with giving alcoholic or other stimulants—would be to regard one side only of the shield, prone to abuse and therefore very likely to do him definite harm.

But to continue consideration of the question what is meant by a disease. As long ago as 300 B.C. Erasistratus of the Alexandrian School of Medicine regarded it as a perversion of health, of the normal processes, and not a

condition contrary or foreign to biological nature; but this was forgotten. In modern times Claude Bernard (1854) spoke of disease as a physiological reaction in altered circumstances, and Clifford Allbutt, since 1871, followed by C. A. Mercier and F. G. Crookshank, pleaded for clear thinking and the recognition that a disease is not a definite thing, like a plant, but a mental abstraction or concept of the reactions of a living organism in certain circumstances. The groups of reactions form distinct pictures in the mind and are labelled by the name of a disease.

WHAT A DISEASE IS NOT.

Before going further it may clear the ground to consider what a disease is not; although a patient is ordinarily spoken of as, say, a case of cancer of the stomach, the malignant growth is not the disease; for disease is the reaction of the *living* body in the form of functional disorders correlated with a cause, whereas the cancerous stomach persists after death. Disease, like health, is inseparable from life, and its nature and causation would no doubt be differently interpreted by those holding the vitalistic and the mechanistic explanations of life.* Further, gross structural change may exist, and yet, as the result of compensatory changes, not cause any disturbance of function or symptoms of disease; conversely, changes such as can at present be recognized by the naked eye and the microscope may be absent in disease, although it is reasonable to imagine that some alterations occur, just as they must in other forms of vital activity. Symptoms, though the manifestations of the reaction and so part of a disease, do not of themselves constitute a definite disease, for they may be due to several causes rather than to one. In the case of infective diseases the exciting cause is invasion of the body by micro-organisms, the toxins of which set up changes in the body and so the resulting reaction called the disease. But the manifestations of the reaction may be regarded as of two kinds and as possibly due to two mechanisms: (1) as Boycott points out, the general symptoms, such as malaise, fever, and headache, common to most infections, are mainly due to substances liberated from the injured cells of the tissues; (2) the manifestations specially characteristic, and so diagnostic of certain infective agents, may be due more to specific bacterial toxins—for example, tetanus toxin, acting directly on the body tissues; or conceivably, as Sidney Martin argued years ago, the bacteria may produce a ferment which acts on the cells of the body so that they manufacture a specific poisonous substance. *Symptoms* have in the past been regarded as diseases—for example, dropsy—and even in our own day it has become recognized that some conditions, such as epilepsy, are collections of symptoms due to different factors; hence it is more correct to speak of the epilepsies rather than of epilepsy. To collections of symptoms occurring in conjunction sufficiently often to render their correlation recognized, but without any constant single underlying cause, the names "syndrome" and "symptom-complex" have been applied; the distinction between a syndrome and a disease, as the words are usually employed, is to be found in their etiology. A distinction has also been drawn between "syndrome," or a collection of symptoms with a functional or anatomical basis in the body, and the more modern word "symptom-complex,"† which implies a series of clinical signs and symptoms without any consideration of their relationship to a lesion or functional disorder of an organ, or a purely clinical coincidence (Cawadias). The word "symptom-complex," which has not escaped criticism as a barbaric mixture of the two classical languages, was, according to the *Oxford Dictionary*, first used in this country in 1897. As Cawadias points out, diseases were really symptom-complexes from Hippocratic times to the era of the anatomico-clinical school of Paris and of Claude Bernard and Johannes Müller (1801–58), when syndromes formed the basis of nosological classification. The term "clinical entity" is often used as synonymous with syndrome or symptom-complex to describe a definite collection of morbid manifestations which may be due to more than one distinct cause, and so is useful as long as the causation is uncertain. It thus avoids the definite statement that the group of symptoms is specific—namely, due to one factor—in other words, a disease in the proper sense of that word. Objection has been raised, especially by the late Sir Clifford Allbutt, to "clinical entity" as a descriptive title for a morbid condition, because it tends to perpetuate the material conception of something analogous to demoniac possession. But though this interpretation may be literally justified, it is not, rightly or wrongly, the meaning widely attached to the phrase.

To sum up, a disease is not a poison, a parasite, an ulcer, or a tumour, for these are causes; it is not a symptom, such as pain; but it is the mental picture of the manifest reactions of a living organism in response to harmful factors, whether derived from outside the body or arising internally.

TRANSITIONS BETWEEN HEALTH AND DISEASE.

As disease is primarily a physiological reaction to stimulating or depressing factors of a harmful character, and a mental concept or "construct" summarizing the events which then occur, it is clear that the line dividing health and the defensive powers of the body from disease may be very indefinite. Thus if the defensive powers are high the necessary reaction may be so short and slight as to be unaccompanied by any symptoms, and the individual is unconscious of the inward struggle that has taken place; this process is indeed constantly in action, and constitutes the resistance of a healthy individual. Truly we stand in jeopardy every hour. In other instances the reaction is more marked, but so rapidly successful that the disease is aborted; it is in cases in which the reaction is prolonged or eventually fails in its purpose that disease is more decidedly present. The leucocytosis in the early stage of infection may be compared with the reactive leucocytic increase during digestion due to absorption of food. Inflammation is an entirely useful and innocent process in the healing of an aseptic wound; indeed, it comes within the four corners of Frédéric's canon of physiology—namely, that "a living being is adjusted in such manner that each perturbing influence provokes to activity a compensating apparatus which brings about neutralization and repair of the damage." No one would call this a disease, but such an inflammatory reaction may gradually become a disease; thus local peritonitis producing adhesions by shutting off an infective focus is a protective or curative process; but general peritonitis is a reaction which so often fails that the causal infection is fatal. Here it may perhaps be mentioned that somewhat similar transitions are seen in diseases which vary in the number of the symptoms; when, instead of all the symptoms recognized as making up the mental concept, a few only are present, the disease is spoken of as larval or fruste; this may be a question of time, the reaction terminating before the initial manifestations are supplemented by those necessary to complete the recognized clinical picture.

With regard to the nature of the exact vital changes which occur in disease, apart from the comparatively gross alterations revealed by the microscope, there is much to learn. The recent advances of knowledge in connexion with the constitution of the atom and the electron hold out promises of possibilities the extent of which it is difficult to forecast. The application of physical chemistry to medicine is clearly of the greatest importance, but is beset with difficulties that attempts to do so deserve sympathetic encouragement, even though they may not yet carry conviction or be confirmed. Auguste Lumière explains health as due to the maintenance of the normal colloidal state, whereas disease is the result of its disturbance causing precipitation of protein from the colloid. When this occurs in the blood stream symptoms of grave disease follow, whereas chronic disease is due to precipi-

* *Augusta Gaskell, who argues that life is due to the permeation by an immaterial system (derived from protons and electrons) of a material atomic system composed of chemical units, believes that the phenomena of cancer "constitute a striking proof" of her hypothesis.*

† *Mercier in 1917 poured scorn on "the terms syndrome, symptom-complex, and other monstrosities made in Germany" as "on a par with the exploit of the servant girl who calls a brilliant flash of lightning 'chronic' or the alienist who calls primary dementia 'dementia praecox.'" But the word (συνδρομή) was employed by the Empiric School of Alexandria, 300 B.C., to describe a series of symptoms (Crookshank, Cawadias), and was adopted by Galen.*

tion in or about the cells of the tissues and organs, the different forms of chronic disease being determined by the organ or organs forming the site of this precipitation. McDonagh in his speculative essays, which are somewhat difficult to follow, brings in the electron; he describes protein particles in the blood, some of which are charged with electrons (negative), others with protons (positive), a condition of fair equilibrium meaning health. When a poison, bacterial or otherwise, comes on the scene, the protons are reinforced and the electrons are withdrawn from the protein particles; as a result the colloid state is affected and protein particles are deposited in any one or more of the four important viscera in the following order—kidneys, brain, lungs, and liver—thus causing disease.

Evolution of Diseases.

As diseases cannot, strictly speaking, be regarded as definite "things," it might seem illogical to speak of their evolution, and it has recently been stated that a serious attempt has not yet been made to apply the doctrine of evolution to the natural history of disease (Gill). No one, however, can fail to be interested in the changes that diseases have shown in the course of time, and in the forms that appear to be new and produced in certain circumstances; as long ago as 1890 an interesting work on *Evolution and Disease* by Sir John Bland-Sutton appeared. Some sort of an explanation of the existence of disease may perhaps be suggested, as a side issue after reading Professor A. E. Boycott's recent presidential address to the Section of Pathology of the Royal Society of Medicine; in it the capacity of self-repair is emphasized as one of the main characters of living organisms, but it is pointed out that this faculty is not, or only in a very slight degree, possessed by individual unicellular organisms. Now little or nothing, if the problematic nature of bacteriophage be excluded, is known about the diseases of unicellular organisms. Diseases and the power of self-repair have both become recognizable as the scale of animal life is traced upwards, and it is conceivable that they are closely allied forms of reaction to stimuli—the one (self-repair) successful, the other (diseases) more or less ineffective. *Diseases are not rigid types, but the more or less unsuccessful reactions to harmful factors, most commonly environmental;* it follows, therefore, that they show considerable variations in their manifestations, especially as the reaction depends on two variable factors—the characters of (1) the host or the "soil," and (2) the unfavourable environmental factor, the "seed."

Changes Associated with Civilization.

1. In the course of his progress from primitive to civilized life man has undergone many changes, and his bodily reactions to external factors, and therefore his diseases, must, like the forms of his virtues and vices, have altered in a corresponding degree, for consideration of his surroundings would suggest that the further man moves from his savage state the more complex will the character of his disorders become. How much a change of type of disease has occurred it is difficult accurately to estimate, for the slow advances of medical knowledge might easily make it appear that the evolution of disease has been more recent and extensive than is really true. There has in fact sometimes been a tendency to exaggerate the differences between the diseases of primitive savages, about which knowledge is deficient, and those of highly civilized inhabitants of large capitals. The ancient records of disease, often ambiguous about the existence of conditions now fully isolated, might easily convey the impression that diseases, such as small-pox and chicken-pox, scarlet fever and measles, became distinct from each other more recently than was actually the case. The comparatively new study of diseases which can be demonstrated in human and animal remains of ancient times, or palaeopathology, in the hands of Fouquet, M. A. Ruffer, Elliot Smith, and Wood Jones in Egypt, and of R. L. Moodie in America, has thrown much light on the antiquity of disease. Thus many affections of bones, arterio-sclerosis, rheumatoid arthritis (2900 B.C.), gout, dental caries and pyorrhoea, pneumonia, gall-stones and renal calculi, bilharziasis, and other still familiar ills that flesh is heir to, have been found in Egyptian mummies. But as regards acute fevers, which from their nature are prone to vary and are much more difficult to identify, help is wanting.

As both nations and their constituent individuals differ in their "constitution" or make-up, partly from heredity and partly as the result of the long-continued influence of their surroundings, their powers of resistance to disease must vary in a corresponding degree. Under certain conditions, such as those of war, famine, and epidemics—for example, of influenza—the vitality of a nation may be so much impaired that factors ordinarily comparatively harmless are enabled to act at an advantage, so that other diseases become frequent. Thus secondary epidemics or diseases which are not in evidence at other times may become prevalent. This sequence may have suggested to Sydenham his conception of "epidemic constitutions"—that is, that during the period of a dominant epidemic other diseases tend to share the characters of that infection. There are, indeed, close analogies between the factors modifying diseases in the course of time and those which appear to be responsible for the outbreaks of epidemics. The diminished resistance of a nation due to the depressing factors—material and mental—inherent in war, destitution, and unemployment, would probably allow micro-organisms previously of comparatively low pathogenic power to become active, and thus help to explain the increased frequency of streptococcal diseases, especially subacute and chronic bacterial endocarditis, and of pernicious anaemia since the great war.

Hereditary deficiency in resistance of the tissues, or of one particular tissue, of races or of individuals may lead to the incidence of particular diseases or to certain forms of those diseases; so that a nervous system weak from congenital defects will favour the attack of an infection, such as that of influenza, on that part of the body—a problem recently discussed by H. P. Newsholme. Hereditary diatheses or morbid proclivities in certain races of mankind lead to the occurrence of special diseases among them; this is best seen in the Jewish nation, which provides most of the cases of amaurotic family idiocy and thrombo-angiitis obliterans; it is further noteworthy that when these diseases do occur in Gentiles the manifestations are less severe and do not come on so early in life, thus suggesting that the inborn tendency is more powerful in the Hebrew cases. The highly nervous make-up of the Jewish race is a factor in disposing them to diseases of this system.

Influence of Environment.

2. Environment influences disease in many ways. It is so clear that climate is a most potent factor that the effects of heat and cold, humidity, absence of sunlight, need not be laboured: in hot countries the presence of special parasites, particularly protozoa, such as the malarial and amoebic organisms, and their carriers or vectors, such as mosquitos, are responsible for the important group of the tropical diseases. On the other hand, an environment, such as that of isolated races, free from some common infections, such as tuberculosis and measles, leaves the inhabitants a virgin soil; but should the infections be introduced, the incidence and mortality of the diseases tend to be very high. This is not so much due to want of innate racial resistance, as might perhaps be thought, but to the widespread absence of any previous individual infection and acquired immunity, or, as Krause persuasively argues, to concomitant changes in the manner of life, approaching those of the more artificial complexities of civilization which lead to physical degeneration of the pure stock of primitive peoples.

Environmental factors are more obviously powerful than heredity in the production of new forms of disease; this was shown, particularly during the great war, by occupational diseases in which the worker is exposed to some poisonous agent, such as trinitrotoluene or tetrachlorethane, in the manufacture of munitions and the varnishing of aeroplane wings with "dope." The branch of Industrial Medicine, already considerably advanced in America, especially in Boston, though originally suggested in this country by George Baker (1767), Thomas Percival (1796), and C. T. Thackrah (1831), and developed by Greenhow (1857), Thomas Oliver, Thomas Legge, and others, supplies many examples

of trade diseases. Another way in which environment brings about disease is by privation of some essential accessory food factor. Study of the "deficiency diseases" and the discovery of vitamins have opened out the path to the prevention of diseases such as rickets, beri-beri, scurvy, and dental caries; and recently vitamin E has been shown to be essential to fertility, its absence being responsible for sterility.

Among the environmental factors bacteria and protozoa are responsible for the majority of diseases. As they are at the base of the scale of living organisms it may be assumed that they are more prone than the higher animals and man to variation and mutation as the result of influences such as food and temperature; and that, at first purely saprophytic, some of them in course of time become parasitic and pathogenic for man. In its early days bacteriology discountenanced bacterial variation, and worked its way on the basis of fixity of type among the species of bacteria. It is now known that there is an enormous amount of potential variation in bacteria, and that a present-day bacteriologist "has not only to define the species of bacterium with which he is working, but the particular form or variant" (Arkwright). Modern work, recently summarized by Dible, shows the morphological, cultural, and serological differences of variants from the normal species—for example, in the Salmonella group (Andrewes; F. Bruce White)—and the probable influence of bacteriophage in promoting variation. The artificial conditions of laboratory cultivation tend to diminish their virulence, though occasionally a reverse action is observed; whereas the passage of pathogenic microbes through a series of animals of the same species enhances their virulence, thus supporting the view long ago expressed by W. H. Welch that bacteria on their part adapt themselves to their environment, just as the host develops a mechanism of defence against them. Clinically it may be noted that an increase in the severity, and not only in the incidence, of an infectious disease, such as diphtheria, may be noticed when a number of individuals are crowded together, though it is true that lowering of their resistance may play some part in this result.

Differences in the clinical manifestations of enteric (typhoid and paratyphoid) fever, dysentery, cerebro-spinal fever, and to some extent of pneumonia, have been proved by bacteriology to result from infection with different types of the typhoid-paratyphoid group, dysentery bacilli (Shiga and Flexner), meningococci, and pneumococci. This distinction of the type of the infective organism is, of course, of far more than academic interest, for it enables immunological treatment to be scientifically and successfully employed. Further evolution of bacterial variations, such as at some time in the past may have resulted in the formation of paratyphoid from typhoid bacilli, might lead to the production of new forms of disease; at the present time it may well be that there are many such bacterial divisions of disease as yet not separated from each other clinically and so still included under a single nosological label. Aberrant forms of infectious diseases would suggest the existence of variations in the causal agent; but here the possibility that mixed infections play a complicating part must be borne in mind. Just as diseases may die out, such as "the sweating sickness" in England in the fifteenth century, so may new diseases arise; syphilis, it seems safe to assume, did not exist in ancient Rome, as such a careful observer as Galen did not describe it or its nervous manifestations tabes dorsalis and general paralysis of the insane. But it may be noted that there is good evidence of its existence in Europe before the era of Columbus, and therefore that it was not introduced from the New World. Among animals hog cholera, unknown before the seventies of the last century, when it appeared in the United States of North America, is an example in support of the view that micro-organisms can and do undergo evolution from a harmless saprophytic condition to one of pathogenic activity.

In balancing the two factors—the soil and the seed—that determine the reactions known as disease, it is interesting to follow the swing of opinion's pendulum between their relative importance; seventy years ago the individual's constitution, diathesis, and temperament were regarded as the essential factors in the causation of illness. When bacteriology came on the scene and progressively revealed the true exciting causes of one infective disease after another, it seemed probable that every difficulty would be clearly solved, and the doctrine of constitution, the elements of which could not be seen under the microscope, faded away into the background as a misty conception, and for a time into almost complete oblivion. But the discoveries of this early stage of bacteriology naturally led to the careful investigation of the defensive powers of the living body against microbic attack; this study of immunology has brought up again the underlying importance of the constitutional factor in disease, which is now attracting investigators in disorders other than those directly due to infection.

THE SIGNIFICANCE OF DISEASE.

To most minds disease is included in the mystery of evil and considered an unmitigated calamity, and in the past has been regarded as part of a system of rewards and punishments. As the existence of a single unicellular organism normally terminates by division into two similar but rejuvenated individuals, these simple cells have been described as immortal, whereas in the higher grades of living creatures death has been regarded as an acquired character, associated with differentiation of the constituent cells and a resulting highly complex mechanism, and as an adaptation advantageous to the race (Weismann); this last—academic—conclusion has been criticized as probably the most perverse extension ever made of the theory of natural selection (Pearl). Death comes either naturally by a gradual exhaustion of the innate endurance and vigour, or unnaturally from accident or disease, which are therefore short cuts to death. From a biological point of view diseases have been regarded as beneficial inasmuch as they weed out the physical weaklings and so make for the survival of the fittest and the improvement of the race. Thus disease kills off the vicious, and, to take a rather special example, gonorrhoea, by sterilizing the prostitute, prevents the propagation of the degenerate; White, indeed, rather unkindly says, "In fact it is open to question whether, taking all things into consideration, the eugenist could do better." Still, many besides the degenerate fall victims, and disease, which has been at work and on its trial in this respect from or before the dawn of history, is too rough and unorganized a method to bring about the survival of the fittest. There will therefore be general agreement with the late Sir Clifford Allbutt's dictum a quarter of a century ago that public health will effect this object better and more permanently than public death. It is unnecessary to labour the evils brought by disease, but it may be well to glance at the other side of the shield and, though to some this may at first sight seem fanciful, to explore the possibility that disease may have good effects—a contention vigorously supported from a technical standpoint nearly a quarter of a century ago by the late Frederick Treves.

As good may come out of evil, it may be worth while to summarize briefly the conceivable ways in which disease on account of associated conditions and of the opposing forces thus brought into play, may be regarded as exerting a beneficial effect. This problem may be reviewed from two aspects: (1) general and sociological, and (2) that of the individual.

Beneficial Effects of Disease in General.

It is not always easy or indeed possible to draw a hard-and-fast line between the normal or healthy on one hand, and the abnormal, which may tend to produce disease or be in itself morbid, on the other hand. That may, in fact, be innocent as well as malignant abnormalities. There is a borderland between health and disease, Allbutt (1924) spoke of as an oscillation about the axis, and it has been said that they are relative terms and that there are various states of health and of disease (W. A. White).

The racial characteristics which, according to Keith, in part depend on the degree of activity of the

glands, may, when exaggerated, become definitely morbid and cause disability. Thus in this country the condition of Mongolian idiocy, first described in 1866 by Langdon Down, the causation of which, though uncertain, may possibly be due to a disturbance of the endocrine balance (Clark, indeed, ascribes it to foetal exophthalmic goitre), reproduces some of the facial characters of the Mongolian race. Pituitary activity, stated to be most obvious among the modern races of the Caucasian or European type, when greatly in excess causes pathological giantism and acromegaly. The occurrence of variations or, more strictly, of "sports" plays a part in the evolution of the race, and among these departures from the average the line of demarcation may be very thin between those exerting a beneficial influence and those definitely morbid. This is familiar in Dryden's lines:

> "Great wits are sure to madness near allied,
> And thin partitions do their bounds divide,"

and as regards this particular example it has been shown by the late Sir Frederick Mott and others, from a study of many pedigrees, how real this association is, and that environment and factors so obscure that in our ignorance they are called chance determine whether this inborn tendency will land the individual in the seats of the mighty, a prison, or a mental hospital.

The variations that are responsible for the evolution of the race are accompanied by others that facilitate disease, and though the latter cannot of themselves be regarded as useful, their occurrence is so commonly associated with that of those making for improvement that they may be regarded as a necessary accompaniment.

Genius and outstanding ability, though often and easily confused, are distinct; ability is, as Galton showed sixty years ago, largely hereditary, and may be associated with a family history of mental instability or defect. But, as compared with ability, genius is a finer and extreme development of the imagination and power of correlation, and may extend out of the abnormal into the pathological. The association of genius with disease of the mind and body has no doubt been exaggerated by the statement that a genius is hardly ever healthy; there are, however, abundant examples to support the contention of Lombroso and others that genius is often closely related not only with criminality and insanity but with other morbid conditions of the nervous system; this combination may occur in the same person, or the association may be shown by evidence of the neuropathic element in the genius's family tree. In the latter instance the genius or specially gifted individual comes of a neuropathic stock, though not himself necessarily degenerate. Enough has been said to show that genius and mental instability may be regarded as variations from the normal mentality. Their morbid manifestations may occur at different times in the same person, periods of definite insanity supervening and passing off; or insanity when it supervenes may close the career.

Geniuses, being usually highly strung, are certainly not immune to common ailments. While disease damages and eventually may destroy the body of the gifted individual, it must colour the mental attitude during the progress. While the usual effect of poisons is necessarily deleterious, some of them, especially in the highly sensitive and those with an idiosyncrasy, may in the early stages, when their irritant effect is predominant, exert a stimulating effect. Alcohol, opium, and morphine, as shown by not a few examples, have been the means by which a genius has been helped to deliver his inspired message. Similarly it has been thought that the toxins of disease may so act on the brain as to lead to the production of masterpieces instead of the more frequent nightmares and delirium. Many literary giants have naturally been tuberculous, and it is an obvious suggestion that their eminence may, in greater or less degree, have been due to, rather than in spite of, their infection. It has also been thought that syphilitic toxaemia played a part in the increased output of brilliant work shortly before its destructive triumph over men like Guy de Maupassant, Friedrich Nietzsche, Heinrich Heine, C. P. Baudelaire, and Paul Verlaine. The occurrence in Nietzsche's *Ecce Homo* of chapters headed "Why I am so clever" and "Why do I write such good books?" certainly suggests that he was already in the stage of exaltation of general paralysis of the insane.

It has been argued that, like alcohol and morphine, the bacterial poisons are responsible for striking ideas and conceptions by paralysing the mechanism normally blocking the external manifestations of an underlying creative power or personality (Jacobson). It is tempting to speculate on the correlation of various organic diseases with the characters of the literary and artistic products of the sufferers, and how far any special trait or tone of expression can be regarded as related to a particular disease. Did the hopeful spirit—the *spes phthisica*—account for the inspiration of some victims of pulmonary tuberculosis, such as Keats, Laurence Sterne, Emily Brontë, and Elizabeth Barrett Browning? There is some evidence from the *Vailima Letters* that when Robert Louis Stevenson's health improved his literary work deteriorated, and this has been explained by the absence of a toxaemic influence. In other instances, such as Francis Thompson (1859–1907), author of *The Hound of Heaven*, and Thomas De Quincey, tuberculosis of the lungs has been complicated by alcoholism or opium addiction; and then, as Jeannette Marks says, the question arises of "germs and genius" or "drugs and genius." How far did dyspepsia or, as G. M. Gould insisted, eye-strain guide Thomas Carlyle's mordant pen, and to what extent was Ménière's syndrome, from which Jonathan Swift probably suffered, responsible for his savage wit?

In some rather special instances an individual's disease has been the means of greatly benefiting his fellow sufferers, as it has made him monstrous kind in the practical sense of providing for their well-being and care; thus Sir Arthur Pearson's (1866–1921) loss of sight was the salvation of the blind in St. Dunstan's, where they were taught not only to earn their living but to bear their cross courageously and cheerfully. Medical men, themselves stricken, have worked for the relief of those with whom they can so fully sympathize: E. L. Trudeau (1848–1910) utilized his own long fight against tuberculosis to promote the open-air treatment of that disease in North America; and it has been said of him that perhaps nothing in the whole field of medicine in the past fifty years in America has done so much directly or indirectly to relieve suffering and extend the years of usefulness of so many people as the principle which Trudeau laid down at Saranac Lake (J. A. Myers). Another example is Mr. Clifford Beers, who, having suffered for years from a severe psychosis, founded the National Committee for Mental Hygiene in the United States.

In his pathetically charming *Confessio Medici* the late Stéphen Paget (1855–1926), who suffered much and greatly loved his fellow men, wrote, "You cannot be a perfect doctor till you have been a patient; you cannot be a perfect surgeon till you have enjoyed" (and he proceeds to justify the somewhat unexpected verb) "in your own person some surgical experience." Many examples could be given of medical men who, as the result of their own sufferings, have been able to throw light on the nature, prevention, and cure or alleviation of their own particular cross.

Pain, one of the commonest manifestations of disease and useful as a warning of its presence, may, as James Hinton (1822–1875) the mystic argued, have uses that we know not of, possibly an unconscious though effective martyrdom for others. In his *Book of the Sorrowful* Hinton was mainly concerned with mental anguish, but with regard to physical pain it may also be wise to admit that there are more things than are dreamt of in our philosophy. Professor Emery Barnes reminds us that "from St. Paul downwards through the ages some of the greatest Saints of God have believed that their bodily sufferings or their bodily weakness has been of immense value in training the spirit."

Lastly, disease, which usually exerts an evil influence on the history of nations, may protect one of two hostile armies from the other by rendering advance and successful

invasion impracticable, or open the way to occupation of a new land—for example, the "providential" pestilence among the aborigines of Massachusetts Bay (1616–20) which enabled the first Pilgrim Fathers to take possession of the land in safety (Krause).

Beneficial Effects for the Individual.

A disease may do good by limiting its victim's activities in certain directions, such as social success or athletic prowess, and so leading him to concentrate his energy and powers on some specialized branch of intellectual work; thus by way of compensation he makes good, or achieves even greater success than he would have thought of attempting when unrestricted in his choice of a life's work. Invalidism necessarily restricts vicious self-indulgence and excess in satisfying the lusts of the flesh, and so may protect against the risk of oth r diseases to which the vigorous are, as a result of their rude health, more prone to expose themselves. This mode of protection is analogous to that probably responsible for the great longevity of women as compared with men.

There are other ways in which disease is a blessing, though perhaps in disguise; the onset of a trivial ailment or the detection of the early signs of disease without symptoms, such as are discovered at a routine examination for life assurance, may so impress the individual that he amends his manner of life, greatly to his future advantage. This warning mechanism was well expressed in the title of Sir William Osler's paper on "The advantages of a trace of albumin and a few tube casts in the urine of certain men above 50 years of age." Another example is the advantage of a raised blood pressure detected in its initial stages, provided steps are duly taken to prevent a further rise which would in time lead to generalized arterio-sclerosis and perhaps granular (arterio-sclerotic) kidneys. With the progress of medicine to its preventive ideal the logical utility of periodical medical examinations of the adult population will no doubt be recognized, and so lead to the detection of the early warnings and signs of impending disease among those as yet unconscious of anything amiss.

It is not an argument worth labouring, but, as certain conditions or reactions, such as emaciation and obesity, are due to their opposites, such as deficiency and excess, one disease may be the antidote to another, the two being, roughly speaking, incompatible. Thus there is a certain amount of antagonism between tuberculosis and gout, and tuberculosis and obesity. Moreover, as is well recognized, a chronic disease may sometimes appear to provide its own cure in this way; thus exophthalmic goitre may gradually pass into the opposite condition of myxoedema, and acromegaly (hyperpituitarism) may be succeeded by hypo-pituitarism.

An acute disease may cure a chronic affection; thus pneumonia may, for the time being at any rate, abolish the movements of chorea, or remove a skin disease of long standing; whooping-cough has long been thought to be relieved by vaccination, and has been known to be benefited by an attack of urticaria (Bury). The influence of an acute infection on a chronic one is probably analogous to the effect of protein shock therapy, in which the injection of a "foreign" protein into the blood stream sets up an acute reaction which in some way increases the protective mechanism against infection; for example, injection of peptone may be followed by much improvement in chronic arthritis. Just as many acute fevers leave behind them immunity for the rest of life, so a modified form of the disease or an abortive attack, which may escape notice at the time, protects the individual from a recurrence of the disease. This is well shown in vaccination against small-pox, and by the observation that people who have had the present mild form of small-pox, sometimes called alastrim and para-small-pox, do not contract the disease itself. Many forms of treatment act by stimulating or supplying the reaction and defensive powers of the patient necessary to repair damage or overcome infection; this was the rationale of Almroth Wright's vaccine therapy, and empirically the method has been employed for ages. The old practice of inserting a seton in the neck, thus creating a local wound or focus of infection, to cure some chronic condition, the similar production of sterile abscesses —for example, by turpentine—to counteract infections elsewhere, and counter-irritation, such as blistering, to relieve the pain in acute diseases, are examples of the attempt to neutralize the morbid reaction of one infection by another and artificially induced reaction.

THE RELATION OF THE NATURE OF DISEASE TO ITS PREVENTION.

Lastly, with regard to the practical bearing of the nature of disease: the ideal of Medicine is the prevention of disease, curative treatment being really a tacit admission of failure in this respect. For the prevention of disease knowledge of its causation and nature is obviously essential. The two great factors in the causation of disease are heredity and environment. Heredity of actual infective disease occurs in only a few instances; but structural and functional defects, especially in the vital resistance, of the body are common and important. Environmental influences cover a wide field, from the gross factors of deficient food, slum dwellings, and general misery, to the ultramicroscopic viruses of infective disease. The preventive measures and remedies, therefore, are correspondingly various. It is unnecessary to refer to the desirability of correcting the economic factors of poverty resulting in unhygienic surroundings, overcrowding, and deficient and bad food and drink; but a word may be said about the importance of universal health education as a means of preventing disease and so preserving the well-being of the nation. The recognition of the need for intellectual education is a duty recognized much earlier by the Government, for it is only since the war, when the Ministry of Health was established, that health education of the masses has really gone ahead. Preventive medicine is every man's business, for it is the active response to the instinct of self-preservation. The distinction, obvious though it be, may perhaps be emphasized between the practice of preventive medicine, in which each individual should be his or her own guardian, and the universal practice of curative medicine, which is inadvisable on account of the inherent dangers when carried out by laymen. It may well be that want of a clear dividing line between personal hygiene and domestic medicine has in the past made medical men hesitate about the advisability of encouraging general instruction in the laws of physiological righteousness, to use Sir Andrew Clark's phrase.

About the fundamental subject of an accurate knowledge of the causation of disease, on which preventive medicine is based, there is yet much to learn. As Sir George Newman has pointed out, it is extraordinary what contributions to medicine have in the past been made by scientific men who were not members of the medical profession. The debt of medicine to the more exact sciences mounts up much more rapidly and is much more obvious evidence now than ever before, and it is obvious that there should therefore be the closest possible association and correlation between the scientific workers in laboratories where discoveries are made and tested, and the clinicians in the wards of hospitals, where the practical application of new knowledge may lead to fresh advances in the prevention as well as the cure of disease. With the specialization inevitable from the enormous advance of knowledge there is an unfortunate tendency for these two classes of workers to plough their own furrows; guidance from those of pure science is of the greatest value in the discovery of the causes and nature of disease; for physics, chemistry, biochemistry, physiology, and pathology touch, overlap, and interlace with each other, and human biology is a good synonym for medicine. To facilitate this close association much can be done by the plan of having the various science laboratories in the same building or group concentrated together; the physiological, bacteriological, anatomical, and pathological departments close to and communicating with the hospital, just as the physiology department is or should be a near neighbour of the anatomical laboratory. The University should have control of the hospital as well as of the laboratories—a combination perhaps yet widely accepted.

VOLVULUS OF THE INTESTINE.

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON, GUY'S HOSPITAL.

VOLVULUS rotation or twist may affect any of the movable viscera, and this accident is especially likely to happen to those organs or parts which are pendulous or more or less pedunculated, such as the pelvic colon, caecum, spleen, retained testis, ovarian cyst, or subperitoneal fibroid. The weight of a tumour, a distended Meckel's diverticulum, or a mesenteric cyst, or the drag of a peritoneal adhesion may start or complete the twist. I have seen several instances of volvulus of the spleen of the omentum, of the gall-bladder causing sloughing, and one instance of rotation of a loose liver causing jaundice by kinking of the bile ducts. Even the stomach is not immune from volvulus; being fixed as it is at the cardia and pylorus, the dilated or distended intervening portion may twist, especially when it is dragged upon by a large spleen or escapes into a diaphragmatic hernia; serious and acute pyloric obstruction has arisen in these ways, and has been relieved by replacement and removing the cause.

In this article I am chiefly concerned with volvulus of the intestine causing intestinal obstruction. Such a volvulus may be *acute, chronic*, or recurrent; it may be simple, affecting only one loop of bowel, or it may be compound, as when a loop of small intestine twists round a volvulus of the pelvic colon.[1] Any part, or the whole, of the small intestine[2] except the duodenum, and any part, or even the whole, of the large intestine except the rectum, may twist (Finney recorded a volvulus of the whole of the colon between the ileo-caecal valve and the pelvic colon[3]), but the common sites of the volvulus are the pelvic (sigmoid) colon and the caecum. Congenital imperfections, especially elongation of the mesentery, such as a long mesosigmoid with a narrow base, or a pendulous and freely movable caecum and ascending colon, are usually determining factors. Visceroptosis with distension and elongation of the pelvic colon associated with chronic constipation, and repeated prolapse of the rectum, also contribute to the causation of volvulus. Injuries, violent twisting movements, and operations may displace and twist the bowels—for instance, the pelvic colon was raised and displaced to the right during an operation for ruptured left extrauterine foetation, the loop was not replaced, and fatal volvulus resulted. The consequences of volvulus are often grave, for obstruction of the vessels may lead to swelling, haemorrhage or *infarction, inflammation, and necrosis* or gangrene of the twisted loop, thus adding to the dangers of intestinal obstruction. Volvulus of the appendix and of Meckel's diverticulum* often causes severe attacks of *inflammation*, or gangrene of the twisted part, with peritonitis and ileus.

SYMPTOMS OF ACUTE VOLVULUS.

The symptoms and signs of acute volvulus, whether of the large or small intestine, are those of acute intestinal obstruction, such as severe spasmodic abdominal pain, characteristic vomiting, complete constipation and collapse, with slow weak pulse and subnormal temperature. Here it is only necessary to point out the special features of volvulus. The history of previous attacks is very suggestive of volvulus, the more acute the case the more severe the pain, and, above all, the more rapid and extreme the distension of the abdomen the more is volvulus to be suspected. Visible peristalsis, when observed, in very large coils is almost characteristic of volvulus of the large intestine, but it is not by any means constant. Volvulus is commoner in the large than in the small intestine, and is especially common in the pelvic colon. With volvulus of the small intestine the coils are naturally smaller and the distension less phenomenal, but the severity of the symptoms is usually extreme, and the march of events to a fatal issue is more rapid unless relief is brought by early operation.

SYMPTOMS OF CHRONIC AND RECURRENT VOLVULUS.

These are chiefly those of chronic intestinal obstruction —namely, recurrent attacks of colic with distension, indigestion, and chronic constipation perhaps alternating with diarrhoea, but without blood in the stools. Fever is usually absent. Sometimes the bowels do not act without the aid of large doses of violent purgatives or enemata or both. Opaque meals, *and especially a* barium enema, may reveal great dilatation and stagnation in the affected loop. An opaque meal is more valuable with chronic incomplete volvulus of the caecum, for an opaque enema may not reach or enter the obstructed loop as the obstruction is more complete at the distal than at the proximal end of the loop. An opaque enema is usually more valuable in the diagnosis of volvulus of the pelvic colon.

DIAGNOSIS OF ACUTE VOLVULUS.

From other kinds of intestinal obstruction volvulus is to be distinguished chiefly by the very acute onset, rapid progress of the symptoms, and particularly by the unusual amount of tympanitic distension of the abdomen, which develops in a very short time. As already mentioned, visible peristalsis in very large coils of intestine is suggestive of volvulus of the large intestine; the twisted dilated caecum is often to be seen lying in the left iliac fossa, and the twisted and distended pelvic colon in the right hypochondrium. There is often a history of previous attacks of colic without fever; the absence of fever tends to exclude recurrent appendicitis, cholecystitis, and diverticulitis. Volvulus of the large intestine is naturally most likely to be mistaken for the far commoner cause of obstruction of the colon—namely, carcinoma of the colon, which causes considerable, but less rapid, gaseous distension. With carcinoma there may be a history of chronic constipation alternating with diarrhoea, with blood and mucus in the stools. Often the diagnosis is not certain until the abdomen is opened, as it should be without delay.

DIAGNOSIS OF CHRONIC VOLVULUS.

Here there is more time and opportunity for investigation. Chronic and recurrent volvulus is most commonly mistaken for chronic constipation, but careful

characteristic of volvulus. Volvulus of the caecum is apt to be mistaken for recurrent appendicitis or appendical colic, but with it there is no fever during the attacks. The dilatation of the caecum, its free mobility and pendulous appearance, should correct the mistake once the abdomen has been opened. In one of my cases of chronic volvulus of the pelvic colon the dilated loop had pressed the stomach into an hour-glass shape; moreover, the gastric symptoms were so severe that the diagnosis made before the operation was hour-glass contraction with duodenal ulcer.

TREATMENT OF ACUTE VOLVULUS.

1. *Acute Intestinal Obstruction due to Volvulus.*

Here the main objects are (*a*) to save life by relieving the acute intestinal obstruction, and (*b*) if possible to prevent recurrence. The mortality of acute volvulus is about 50 per cent., and is so high chiefly from delay and attempting too much at the emergency operation. A long right paramedian incision is made in the lower abdomen to give a good view and plenty of room to deal with the distended bowel. It is often necessary to deliver the affected loop, but this may be impossible without first letting out gas with a needle, or trocar and cannula; sometimes it is better to incise the loop over a sterilized basin, and to make use of this incision in performing a colostomy or caecostomy. The twist is undone and valvular drainage of the loop established with a soft rubber tube of one-third of an inch internal diameter, which passes through a separate stab wound in the parietes, so that the exploratory wound may heal by primary union. The drainage may so reduce the size of the affected loop of bowel and fix it to the parietes that recurrence of rotation may not take place, and the need of a secondary and perhaps severe operation is thus avoided (Cases I and II). In some cases of volvulus of the pelvic colon it is enough to pass up a rectal tube, guided into the distended loop by a hand in the pelvis. The tube is kept in and sewn to the anus. When the bowel is gangrenous it must be resected, and sometimes the channel can be immediately re-established—for instance, the gangrenous caecum is excised and the ileum, about six inches above the ileo-caecal valve, is joined to the transverse colon. As a rule radical operations have to be deferred until the immediate peril has passed.

2. *Chronic Volvulus of the Intestine.*

This condition may be treated by: (*1*) excision of the twisted loop; (2) short circuit; (3) fixation of the loop, with or without temporary drainage. As a rule excision is the best method because it makes recurrence impossible, and prevents the troublesome accumulation of faeces and gas in the dilated loop; but short circuit is sufficient and less dangerous in selected cases. Examples of these methods are given below (Cases III and IV).

Fixation of the loop of bowel by suture to the parietes is difficult owing to the length and position of the loop. How can the long large loop of pelvic colon with a narrow base or pedicle be fixed without fear of recurrence or the making of pockets, apertures, or bands, for the development of other forms of intestinal obstruction later on? Recurrence took place in two of my cases of volvulus of the pelvic colon.[1] In both of these the loop had been fixed to the abdominal wall. Shortening the mesentery after the method of Senn has been successfully used in some cases. The mesentery is "folded" upon itself in a direction parallel to the bowel, and the apex of the fold is sewn to the root of the mesentery without interfering with the blood supply of the bowel. It is evident that this method is not always applicable to such parts as the abnormal pelvic colon, where the loop is long and the base is short. For volvulus of the ileo-caecal region I believe that either excision or short-circuiting is better than fixation, which may cause future trouble by adhesions or kinking.

The following cases may serve to illustrate some of the difficulties of the diagnosis and treatment of volvulus.

CASE I.—*Volvulus of the Caecum: Acute Intestinal Obstruction: Caecostomy: Recovery.*

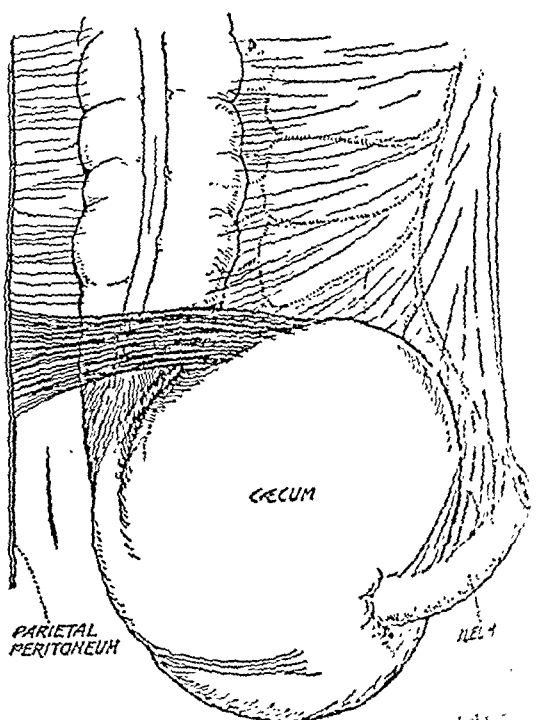
A married woman, aged 45, first came to me in January, 1922. She had suffered from chronic indigestion for years; this had been attributed to visceroptosis, for which she had worn a Curtis belt. She is said also to have suffered from left hydronephrosis. X-ray examination for stone had been negative. She was very anaemic, and was tender over the appendix. In February, 1922, the abdomen was explored through a right paramedian incision. The appendix was very long, kinked, and chronically inflamed, and was removed. There was an old, but still active, ulcer on the anterior wall of the duodenum, stenosing the latter. There were so many adhesions that a local operation was not considered safe, therefore a posterior gastro-jejunostomy was performed. There were no gall-stones; the caecum was dilated. She was well for over five years.

On May 15th, 1927, at 10 p.m., she was seized with very severe abdominal pain, and spent the night walking about the room in great distress. Dr. W. was called in on May 16th. Enemata failed to act, and no flatus was passed. Visible peristalsis was noticed, and an immediate operation advised. This was carried out the same day at 6 p.m. A right low paramedian incision was made, the rectus being displaced outwards, displaying a very large distended coil of large intestine, which was found in the lower half of the abdomen; this was cautiously delivered, and found to be the caecum in volvulus, which was very large, and had made two complete clockwise rotations to the left; this had completely obstructed the ascending colon, but not the end of the ileum. The volvulus was uncoiled, and the contents of the caecum were, with some difficulty, pushed on into the transverse colon, but to prevent paralytic distension, and especially to avoid recurrence of the volvulus, a valvular caecostomy was performed. A long rubber tube, with an internal diameter of one-third of an inch, was passed through the abdominal wall at a stab wound one inch internal of the right anterior superior spine. The end of the tube was open, and a side hole was made close to its extremity, which was introduced into the caecum through the anterior muscular band, after a large pouch of caecum had been emptied and clamped; it was fastened to the sides of the incision in the caecum by a catgut stitch, then the small incision containing the tube was inverted by three purse-string sutures of fine catgut, thus making an ink-bottle or continent caecostomy. The caecum was next drawn into contact with the parietal peritoneum, and the tube was tied to a stitch in the skin. The paramedian incision was then completely closed in layers.

It is interesting that in this case it required two complete rotations to produce obstruction of the ascending colon and caecum; there was no band extending from the right flank to the front of the ascending colon to facilitate obstruction. The patient did well, and was seen in perfect health in September, 1928.

CASE II.—*Chronic Volvulus of the Caecum and Chronic Intestinal Obstruction: Anastomosis of the Caecum to the Transverse Colon.*

Miss X had suffered since childhood from very severe constipation with attacks of abdominal pain without fever. Radiographic examination suggested adhesions in the right iliac region, and



Volvulus of the caecum. The twist is more often clockwise, to the left.

it was thought that she had chronic appendicitis, and [illegible] a laparotomy. The operation was done on April 5th, [illegible] appendix was oedematous and white; there were no [illegible] about it or the intestines, but the caecum was very [illegible] and lying low in the pelvis; it was freely movable and [illegible] with the lower end of the ileum, and clearly caused [illegible] upon the ascending colon, the lower part of which was [illegible] There was a white mark on the ascending colon indicating [illegible] of the former twistings, just below adhesions to the [illegible] The appendix was removed, and an anastomosis was made [illegible] the front of the lower end of the caecum and the [illegible]

of the transverse colon, the anastomosis being about three inches in length. *The patient has done very well since the operation, the constipation and pain being apparently cured.*

CASE III.—*Recurrence of Acute Volvulus of the Pelvic Colon in Spite of Colostomy.*

A lady, aged 61, a patient of Dr. B., in 1906 *was operated upon* for acute intestinal obstruction. After making an incision in the left linea semilunaris, the surgeon accidentally opened a greatly distended colon. It made a noise like a bursting tyre, and discharged a large amount of gas and faeces. He tied in a Paul's tube at once, and the patient gradually recovered. Malignant stricture of the sigmoid was diagnosed, and a bad prognosis was given; but after some weeks the bowels began to operate naturally and there was a good deal of difficulty in keeping the colostomy open. After six months the fistula was allowed to close, and to everybody's surprise the patient made a complete recovery, except for some weakness in the abdominal wall at the site of the colostomy. The bowels acted regularly with the aid of an occasional aperient. She had no more colic, *and she never passed any* blood or mucus. The abdomen, however, has ever since, and for *some time* previously, been somewhat distended. On February 27th, 1912, it became more distended, and the patient had a good deal of pain in the lower part of the abdomen, especially on the left side. Since then the swelling has rapidly increased. All purgatives have failed to act, and enemata have also been *ineffectual*. A rectal tube could not be passed more than six inches. No growth could be felt. An enormously *distended coil* of intestine could be seen extending along the course of the transverse colon, above *the umbilicus* and down to the left flank.

I saw *her* on March 1st, at 8 p.m. In view of the past history and the presence of the greatly distended coil a diagnosis of volvulus of the sigmoid was made, and an operation was performed *the same evening*. A very large coil of bowel was found occupying the pelvis, *the* left flank, and also the middle part of the abdomen, extending almost to the liver. *A band was passed* into the pelvis and a rotation of the sigmoid loop was made out. At the attachment of its mesentery radiating ridges were felt. The incision was enlarged and *the loop* was gradually delivered. The coil was longer and larger than a coat sleeve. The twist could not be completely reduced *owing to the great distension* and extensive adhesions at the site of the colostomy. A trocar was thrust into the middle of the distended bowel, and a very large amount of gas at *once* escaped through the attached rubber tube; a little faeces also came away. The opening was closed with a purse-string suture of thread as the cannula was *withdrawn*. An attempt was made to sever the attached piece of colon from the sac of the hernia. *In doing this*, however, a small opening was made into the bowel. It was therefore *decided* to tie a glass tube *into this opening* for temporary drainage only. *A loop of* bowel above this was placed vertically behind the abdominal incision, which was closed with mass salmon-gut sutures not perforating the peritoneum, so *that the bowel might* get extensively attached to the parietes to prevent further rotation. The tube *was removed* a few days later and the patient made a good recovery, and was well three years later.

It is certain that the volvulus was not reduced at the first operation, but the drainage and shrinkage of *the distended loop* served to re-establish the channel after some weeks. Later on distension increased, and history repeated itself.

CASE IV.—*Chronic Recurrent Volvulus of the Pelvic Colon: Resection: Recovery.*

A boy, aged 14, was in 1918 admitted to Guy's Hospital under my care for repeated attacks of pain in the left loin. In 1915 *he had a definite and severe attack of appendicitis*, with fever, pain, and local tenderness in the right iliac fossa; he was in bed for three weeks, and an operation in the quiet period was advised.

For two and a half years *before admission* the boy had suffered from severe attacks of pain in the left loin, relieved by rest in bed, hot bottles, and a dose of castor oil; there was neither vomiting nor any abnormality of the urine or urination. Left renal or ureteral calculus was suspected, but radiography and urinalysis were negative. *The attacks recurred* more frequently and became more severe during *the latter part of 1919*. In February, 1920, the boy was readmitted for further investigation, but no evidence could be *obtained* of any disease or obstruction of the left kidney. Radiographic examination of the gastro-intestinal tract showed no [illegible] some delay in the transverse colon, which [illegible]ted. The abdomen was explored and a [illegible]ndix was removed. All the large intestine [illegible] the caecum, and transverse and pelvic colons; *the latter* was elongated and hypertrophied, but not obstructed, *therefore it* was not thought wise to resect it without consulting the mother and unless the *attack* recurred.

The attacks, however, *increased in frequency and severity*; therefore, at the end of April, 1920, the abdomen was reopened, and the pendulous and *now twisted* loop of pelvic colon was excised, an end-to-end union being made. The patient made a good recovery and has been *able* to carry on his work as an engineer ever since, but he still gets *pain* in the left loin if he *allows his bowels* to get constipated; this happens when he is rowing and racing upon the Thames.

PROGNOSIS.

The mortality of volvulus is very high. Thus in Corner and Sargent's[5] collection of 57 *cases*, 19 recovered and 21 *died* after operation; the remainder died *without* operation. In the records of Guy's Hospital for the five years 1920–24 Mr. B. L. Laver found 11 cases of volvulus, 6 of *the small* and 5 of the large intestine, with 5 deaths—a mortality of 45 per cent. in 74 cases. Quick and efficient work and drainage of the distended loop and of the intestines above the obstruction, and *not* attempting too much in the critical acute stage, are very important elements in the success of *the operation*.

THE USE OF ULTRA-VIOLET RAYS IN DISEASES OF THE NOSE AND THROAT.*

BY

ALBERT EIDINOW, M.B., B.S.Lond.,

(From the National Institute for Medical Research, Mount Vernon, Hampstead.)

THE biological action of light is primarily due to photochemical reaction. Waves of light are absorbed by living cells and produce photo-biochemical reactions which influence the whole organism. All living cells are sensitive to the ultra-violet rays from 3,100 to 2,500 A.U.; furthermore, the living cells can be made sensitive to the infra-red, visible, and *long* ultra-violet rays by the addition of certain dyes and chemical substances called "light sensitizers." When a normal tissue, such as the skin, is exposed to a source of light emitting numerous waves of light, each group of waves penetrates through the depths of the tissue to varying degrees and has a different biological action. The near infra-red, visible red, and *yellow* rays penetrate beyond the blood vessels in the skin and heat the tissues; as a result vaso-dilatation and hyperaemia are produced. The green, blue, violet, and long ultra-violet rays *penetrate* to a *smaller* extent, and are absorbed by the haemoglobin pigments of the cutaneous blood. The long ultra-violet rays excite a greenish fluorescence of the skin, and are selective in their behaviour to the light sensitizers. The ultra-violet rays from 3,100 to 2,500 A.U. penetrate to the superficial layers of the living epidermal cells. They excite a green *fluorescent light in* the horny layers of the skin, and, having a rapid lethal action on the living cells, produce a characteristic erythema *of the skin* at the site of irradiation.

The erythema dose of light produces a marked local hyperaemia and excites a local white cell infiltration of the epidermal tissues. The endothelial cells are swollen and enlarged, and the transudation of fluids through the walls of the capillaries is altered. The exudation of plasma produces an intradermal oedema of the tissues at the irradiated area. The minimal erythema dose of ultra-violet rays applied to the skin, the peritoneum, abdominal viscera, or subcutaneous tissue increases the bactericidal properties of the shed defibrinated blood tested *in vitro*. The maximum effect is obtained by irradiation of 20 to 30 sq. cm. per kilogram of weight. This bactericidal effect *originates locally* at the site of irradiation, and is *carried* by the blood stream into the general circulation. *These* results support the theory that ultra-*violet* rays have *a* photo-biochemical action on the living cells and produce a substance which has bactericidal *properties*. The local effect of ultra-*violet* rays increases the immunity of the skin. This may explain the beneficial action of the local irradiation of lupus lesions, and *is due to the* increased leucocytic infiltration *and the production of a bactericidal photo-biochemical* substance.

Workers at the Copenhagen Light Institute have developed the use of the short-flame *carbon arc*, and have successfully treated many cases of lupus *vulgaris* of the skin and mucous membranes. The ultra-violet rays emitted *from this source of light* are mostly long rays. In their *technique* the *whole surface of the body* is exposed to light for twenty minutes to two *hours twice or three times* a week. This technique is only suitable for *chronic* types

* Read in the Section of Laryngology, Royal Society of Medicine.

of disease and in non-febrile conditions. Although many excellent clinical results have been obtained by various clinicians, the experimental evidence obtained from the observations of the immunity of the skin following irradiation and the study of the haemobactericidal response to light suggests that overdosage and excessive exposure have been frequent. The application of an erythema dose of rays renders the irradiated area immune to further reaction for three or four days; this is due to the protective screening action of the exudates in the inter-epidermal tissues. During the stages prior to desquamation the skin is still immune to radiation, since the dead epidermal cells screen off the biological active rays. During desquamation the exposed epidermal tissue is hypersensitive to light, and an irregular action results, demonstrating immune and hypersensitive areas. From these observations it seems right that a period of ten to fourteen days should elapse between the exposures of any given areas of skin. In this way the skin can be kept sensitive to ultra-violet rays for a long period, and excessive heating of the body by prolonged exposure is avoided.

The Finsen Light Institute at Copenhagen claims as good results as Rollier obtains with open air and sunlight. The possible errors of the technique with ultra-violet rays with short-flamed arcs are: (1) The area of skin exposed is too big. (2) The skin is rendered immune to ultra-violet rays. (3) The body is overheated by prolonged exposures. (4) It is unsuitable for febrile diseases. (5) It is laborious and expensive.

From these observations I have adopted a special technique of general treatment with lamps emitting ultra-violet rays shorter than 2,970 A.U., which I have called "short ray" therapy.

1. The source of light is a quartz mercury vapour lamp, and at later stages, when pigmentation has developed, metal-cored 30-ampere carbon arcs.
2. The surface area of skin exposed is roughly equal to one-sixth of the surface area of the body.
3. An interval of ten to fourteen days is allowed between irradiation of any given area of skin.
4. Irradiation is conducted two or three times a week.
5. The minimal erythema dose is applied, and the skin is kept in a "light-sensitive" state during the whole period of treatment.

The "general" irradiation of the normal skin improves the health and body resistance. Early cases of lupus of the skin, nasopharynx, palate, and larynx have been healed by these means. The cases in which chronic ulceration and hard scar fibrous tissue are present are more resistant. Many catarrhal and inflammatory conditions of the mucous membrane are due to general failures of health, associated with a secondary anaemia and vasomotor disturbances. Light has often proved a valuable help and has improved these conditions.

The healing of septic wounds and the repair of granulation tissue are accelerated by general irradiation. In cases of subacute disease and acute inflammatory conditions the cautious use of irradiation of the skin can be helpful. In these types of condition the application of the minimal erythema dose and exposure of a small area of skin to light is a safe technique of treatment. General light treatment has been successfully employed as a post-operative measure, and accelerates the healing of septic wounds and young granulation tissue.

The local treatment of a lesion with correct dosage of light accelerates repair. Some early investigators have maintained that a direct bactericidal action was obtained by means of the water-cooled Finsen-Reyn arc lamp or the mercury Kromayer lamp, but this is an erroneous impression, for serum and lymph greatly impede the penetration of the bactericidal rays.

Excessive dosage produces necrosis of the tissues and extensive oedema, which may cause a spreading infiltrating cellulitis. This applies mainly to subacute conditions when the granulation tissue is vascular, but is uncommon with chronic fibrous ulceration such as is seen in old-standing conditions of lupus vulgaris. The careful dosage in local irradiation, producing a mild erythema reaction and avoiding excessive damage to the tissues, will hasten the healing and repair of many types of septic wounds.

The normal mucous membrane is about three times as sensitive to light compared to the normal white skin. Many cases of tuberculous disease of the mouth, throat, or nose can be healed by general light treatment of the skin. As a rule they react more favourably and quicker than the skin, since the granulation tissue is more vascular and ulceration does not contain hard, old fibrous tissue. Strandberg has claimed good results in the treatment of tuberculous disease of the larynx. Local treatment to the mucous membrane accelerates repair and regeneration of granulation tissue. The application of local light through the mouth to the pharynx and larynx necessitates an apparatus by which the effects of radiation are rapidly obtained. Irritability and pain are prominent symptoms, and only a rapid form of treatment is practicable.

The use of quartz rods and applicators to transmit the rays of light to the site of infection are unsatisfactory, as the intensity of radiation is reduced, and the apparatus becomes cumbersome and is impossible to use for a practical therapeutic exposure. The same criticism applies to the use of reflected light from mirrors. The water-cooled throat lamp (made by the British Hanovia Quartz Lamp Company) is based on the same principles as the water-cooled Kromayer mercury lamp, but is sufficiently small to be readily inserted into the mouth, pharynx, and naso-pharynx. The intensity of ultra-violet rays emitted is sufficient to produce an erythema reaction after 60 seconds' exposure of the mucous membrane. A quartz envelope surrounds the burner, and can be easily removed to clean the lamp.

Local anaesthesia with eucaine and cleansing of the irradiated area are necessary before light is applied to the mouth. The reactions of the mucous membrane are similar to those seen when the skin is irradiated; erythema and oedema are evident, and massive exposure produces necrosis and blistering of the mucosa. Since the mucous membrane is more sensitive to light than the skin the regulation of dosage must be made with great care. Excessive dosage can cause a spreading infiltration and acute inflammation which will produce a general reaction of the body, with increased temperature and malaise. In cases of tuberculous disease of the larynx and palate the lungs are often involved, and the irradiation of the local lesion in the mucous membrane may cause reaction of the lung infection. Careful supervision of the lung is imperative. The irritability and pain associated with ulceration of the lesions are rapidly diminished after treatment.

Local treatment is applied every ten to fourteen days. The combination of exposure of areas of the normal skin to irradiation twice or three times a week and local treatment every ten to fourteen days to the lesion has proved successful in resistant cases of lupus and tuberculous disease of the palate, pharynx, and larynx.

Further research on treatment by means of sensitized and ultra-violet radiations emitted by high-frequency current is in progress.

RADIOGRAPHIC FINDINGS IN 347 PAINFUL SHOULDERS.

BY

JAMES F. BRAILSFORD, M.D.B'ham, M.R.C.S.Eng.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

For the purpose of this paper I have examined the radiographs of 347 patients who came for *x*-ray examination on account of pain in the region of the shoulder-joint during the past three years.

I have not included any patients attending the casualty department with a history of recent injury to the shoulder. On the other hand, many patients complaining of painful shoulder would not be sent for an *x*-ray examination as the clinical investigation revealing definite signs of pathology would furnish sufficient explanation for the symptom. I have seen several patients whose chief complaint was pain around the left shoulder and arm in acute exacerbation in whom the only lesion to be found was a cholelithiasis.[2(d)] In many instances the pain appeared to be due to toxic absorption, and the

was sent only for a radiographic examination of the teeth, sinuses, etc. Frequently the radiograph of the painful joint showed no bone or joint change, but definite apical abscesses or evidence of sinus infection were detected.[1]

Sarcoma	2	1	1	—	4
Myeloma	2	—	—	—	2
Exostosis	—	2	—	—	2
Osteomyelitis with arthritis	1	1	—	5	7

The table shows that the most frequent site of injury or arthritic changes to appear on the radiograph is the acromio-clavicular joint. Most of the shoulder-joints which had been dislocated showed definite changes. The most common evidence of arthritis in the shoulder-joint shown on the radiograph was pointing and irregularity of the articular margins.

The areas in the head of the humerus described by A. L. Fisher[4] as cavities, which he believes to be due to local necrosis brought about by amoebic infestation, and as being characteristic of the first signs of osteo-arthritis, I have regarded as varieties of the normal cancellous structure of the head of the humerus, because they are found in many patients in whom there is no suggestion of osteo-arthritis. Fisher admits that such areas are found when there is no other radiographic evidence of arthritic changes. Apart from the pensions hospitals, definite marked osteo-arthritic changes, as shown by indications of erosion and eburnation in the shoulder-joint, were seen in only one case.

Loose bodies were seen in only 3 per cent. of the total cases. In all these cases there was a definite history of severe injury. In five a definite history of dislocation was obtained, and in these cases the radiographic appearance suggested detached fragments or calcification of particles of damaged joint structures. The remaining three suggested calcareous deposits in the subcoracoid and subdeltoid bursae.

No case of the condition of osteo-chondromatosis occurred in the series. The loose bodies in this condition usually contain sufficient calcium to permit of their demonstration by x rays. Hagemann[8] recorded a case in which the bodies were shown in the shoulder-joint, in the bursa beneath the coracoid process, and in the synovial sheath of the tendon of the biceps. Albee[1] recorded a case in which sixty-four joint mice were found in the shoulder of a patient, aged 33, who gave a history of trauma thirteen years before. Hugh Jones[6] records a case of osteo-chondromatosis of the shoulder-joint of a girl of 20, in whom the symptoms extended back twelve years. They were removed, but a further radiograph sixteen months later showed that a new collection had developed.

The presence of "rice" bodies in the joint usually cannot be detected on the radiograph, and there was no record of these bodies having been found in the shoulder-joint or bursae in this series. Mumford[10] records a case in which a large number of rice bodies, not shown on the radiographs, were removed from a large subdeltoid bursa, the walls of which microscopically suggested the diagnosis of tubercle.

In my experience recurrent dislocation of the shoulder is not often associated with loose-body production.

Fractures and Dislocations.—The numbers recorded under these headings refer only to those cases in which the fracture or dislocation had not been suspected or diagnosed at the time of the injury, and had been found only when, owing to the persistence of the pain in the shoulder, and sometimes at the demand of the patient, a radiographic examination was made. The majority of the bone injuries so discovered were limited to the greater tuberosity of the humerus.

Lesions in the Soft Tissues.—The radiograph does not give any evidence of inflammatory conditions of the muscles, tendons, or bursae unless they have existed for some time and calcium has been deposited in or upon the damaged structures. I reported two cases of infestation with *Cysticercus cellulosae* to a meeting of the Electro-Therapeutic Section of the Royal Society of Medicine in 1925.[2(c)] These patients complained of "rheumatic" pains, and radiographs showed calcified cysts throughout the musculature of the shoulder. I referred to similar findings by Stieda, Saupe, and Pickler, and to a case of trichinosis reported by Levy Dorn in 1923 in which the radiographs showed numerous minute calcified cysts throughout the musculature.

ASTHMA IN CHILDREN.

BY

R. H. SIMPSON, M.D., AND KENNETH STONE, M.D., M.R.C.P., M.R.C.P.,

ASSISTANT PHYSICIANS, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.

ASTHMA occurs in young children more frequently than is generally supposed, for in infancy the clinical picture often differs from that seen in adult life: catarrhal features are much more in evidence and tend to obscure the diagnosis.

CLINICAL TYPES.

Above the age of 5 or 6 years the attacks are usually of the adult type, occurring at irregular intervals, and characterized by the sudden onset of dyspnoea, usually in the early hours of the morning. There is often considerable distress, the face is pale or cyanosed, the chest more or less fixed in the position of inspiration, and expiration is difficult, prolonged, and wheezing. Fever is usually absent. Cough is dry and hard at first, but, as the attack passes off, it becomes loose, and is associated with the appearance of bubbling rales in the chest. The duration

of these attacks varies from a few minutes to a few hours. If they are frequent and severe they may occasion considerable impairment of health, but as a rule the patient remains well in the free intervals unless structural changes have been produced in the lungs.

In infancy the manifestations are often different. There is sometimes no spasmodic dyspnoea, and the attacks resemble acute bronchitis. They are characterized, however, by a sudden onset, a moderate or slight degree of fever, a brief duration of only one or two days, and by a rapid subsidence. They recur at irregular intervals in the same way as do those of the adult type. More often the onset is less acute and sudden, and cough, dyspnoea, and wheezing respiration may sometimes persist for several weeks, with exacerbations at night. Sibili are plentiful in the lungs, and after prolonged or repeated attacks there may be evidence of emphysema, which often disappears completely if the asthma can be relieved. Milder forms are often seen, in which a brief cold is followed by cough and wheezing for one or two days.

ETIOLOGY.

Asthmatic attacks are more common in boys than in girls, and may occur at any age, even during the first few weeks of life. John Thomson[1] records that of 100 cases occurring in children under 14, no fewer than 29 arose before the age of 2, and 31 between the ages of 2 and 4—that is to say, 60 per cent. began in the first four years of life. There is often a history of asthma in other members of the family, but this is by no means always the case.

The sudden onset of classical asthmatic attacks with expiratory dyspnoea, distension of the lungs with air, and evidence of catarrh has long suggested that the anatomical basis consists in spasm of the bronchial muscles, associated with swelling and exudation from the mucosa. It is this latter feature which seems to predominate in infancy. As long ago as 1910 it was pointed out how closely these conditions resemble those which are found in young guinea-pigs dying of anaphylactic shock, and it is now generally admitted that asthma is a manifestation of allergy, occurring in patients who have either inherited or acquired a hypersensitiveness to certain protein substances. The rapid improvement which follows the injection of adrenaline affords additional support to this hypothesis. In most cases the offending material is probably inhaled, but it may also be ingested, or absorbed from some septic focus. There are many instances in which this hypersensitiveness is undoubted. For example, there are patients who develop asthma only after contact with some particular material—it may be the dandruff of animals (notably of horses or of cats), the pollen of certain grasses or flowers, or some foodstuff, such as egg. If the offending substance is avoided the attacks cease, only to return after fresh exposure. Often, however, neither history nor cutaneous tests with likely proteins reveal any particular cause, and the precise nature of the allergen remains unknown. However, Professor van Leeuwen and his associates[2] have produced much interesting evidence as to the common sources of such bodies. He divides them into two classes: (*a*) those occurring in the dust of the general atmosphere, and (*b*) those in household dust, to which many asthmatics seem to be particularly susceptible. It is interesting to note that allergens of class (*b*) do not seem to occur in hospitals or similar institutions, and that asthmatics who are susceptible to them remain well, provided that they do not sleep in private houses. By placing patients in specially constructed chambers from which all dust is excluded Professor van Leeuwen has been able to keep them from attacks. This work adds point to the well-known fact that people who suffer from asthma in one locality may be quite free from it in another.

CLINICAL DIAGNOSIS.

It is in the infantile forms that the diagnosis is most difficult, and such cases are often overlooked or mistaken for a simple bronchitis, particularly if prolonged observation is impracticable. The points which attract attention in the bronchitic type are the sudden onset with dyspnoea and wheeziness, the brief duration, and the rapid subsidence, followed by recurrence at irregular intervals. The milder and much more common cases with a brief catarrhal onset are more easily recognized, especially when the succeeding period of wheeziness is short and the attacks recur frequently. Many of the more protracted cases have been diagnosed as mild bronchitis with added bronchial spasm, or have been described as spasmodic bronchitis. There seems little doubt, however, that they are genuinely asthmatic in origin.

Attacks of the adult type are usually quite characteristic. Sometimes, however, other possibilities have to be considered. The sudden onset may arouse the suspicion that a foreign body has lodged in the respiratory tract. The dyspnoea of laryngitis—particularly of diphtheritic laryngitis—may sometimes suggest asthma, but here some evidence of laryngeal obstruction is rarely lacking. The rare condition known as thymic asthma is unfortunately named. Its etiology is, of course, entirely different from that of true asthma, the dyspnoea being caused, it is alleged, by the pressure of a large thymus on the trachea. It is important to remember that in all these conditions the chief difficulty in breathing occurs in inspiration rather than in expiration—the reverse of what obtains in a genuine asthmatic attack.

There are two conditions which, when present, help to confirm the diagnosis of asthma. These are (*a*) urticaria, and (*b*) a definite eosinophilia. There is also a therapeutic test which, although not infallible, is very valuable. This consists in the prompt improvement which so often follows the subcutaneous administration of adrenaline. This response is less definite in long-standing than in recent cases.

TREATMENT OF THE ATTACK.

The patient is put to bed, if not already there. From 5 to 10 minims of a 1 in 1,000 solution of adrenaline are injected subcutaneously. Relief from the bronchial spasm comes quickly, usually well within a quarter of an hour, though it may not last long enough for the attack to be abolished in this way. Next, it is well to cover the chest, front, and back with a mustard poultice until the skin is red; this takes about a quarter of an hour. After removing the poultice, grease the skin. The treatment may be repeated in three or four hours, provided the hyperæmia produced has subsided. A diaphoretic expectorant mixture, such as that recommended by John Thomson, namely:

Vin. ipecac.	ɱv
Sp. æth. nit.	ɱv
Liq. ammon. acet.	ʒss
Aq. cinnamomi	ad ʒj

should be given every four hours. When the acute attack is over, potassium iodide, 1 to 4 grains, in a mixture containing 5 minims of tincture of belladonna and 5 minims of ethereal tincture of lobelia, should be given thrice daily until the chest is clear.

PROPHYLACTIC TREATMENT.

We wish to dwell chiefly in this article on the treatment of the underlying conditions which predispose to asthmatic attacks, for if attacks can be reduced in severity, and the interval between them prolonged, the greatest danger to the child—emphysema and chronic bronchitis—may be averted.

Before considering treatment of the allergic state, it is essential to carry out a thorough examination of the upper air passages. A chronic nasopharyngeal catarrh, probably sustained by infected tonsils and adenoids, or chronically inflamed nasal sinuses, demands adequate treatment.

Asthma is, as we believe, a *symptom* resulting from allergic reaction in the bronchioles; the prevention of these reactions may be considered under two headings.

Avoidance of Contact with the Allergen Responsible.—It is probably true that if contact with the responsible allergen could be avoided for many years, the patient would become spontaneously desensitized. In any case, if it is possible to keep the child away from the offending substance for long periods, the diminished frequency of asthmatic attacks will go far to prevent structural damage to the lungs. Prophylactic treatment in this direction must therefore be given fullest consideration. In

rare cases careful observation of the conditions immediately preceding an attack of asthma may lead to the discovery of the substance responsible; it may be the presence of a cat, or a horse, or a feather pillow, or the ingestion of some food. These cases are very rare, but in them prophylaxis by avoiding contact with the substance to which they are sensitive is not, as a rule, difficult. If there is no such clue to the specific allergen responsible, it is scarcely worth while to attempt its detection by protein skin tests. The results in almost all cases are equivocal: in some cases a reaction is obtained with a large number of substances, in others with none of the substances used. There is, however, good reason to believe that in the great majority of cases the allergen which is causing attacks of asthma is inhaled. In the absence of a specific diagnosis, it is our duty then to investigate the effect of environment of the case. If any locality is found where the child is free, or comparatively free from attacks, let him stay there for as long periods as possible. We know that a large proportion of asthmatics are free from attacks at high mountain altitudes. Many London children are free from attacks in the country.

Attempts at Desensitization.

(*a*) *Specific Desensitization.*—In those rare cases where the offending substance is discovered, and where avoidance of contact with it is difficult, specific desensitization may be tried. Repeated subcutaneous injections with the substance, beginning with minute doses which are very gradually increased, may ultimately so reduce sensitiveness that the patient remains symptom-free. This is a method of treatment not to be lightly undertaken; it should be left to experts. Such patients are often highly sensitive, and it is easy to precipitate severe symptoms resembling anaphylactic shock in animals. Dudgeon[2] has recorded the case of a lady who had suffered from severe horse asthma from childhood. Deciding to attempt specific desensitization, he gave as an initial dose 0.25 c.cm. of serum. Within five minutes of the injection she was comatose, with signs of severe pulmonary oedema and heart failure. A reaction may occur with such alarming suddenness that an injection should never be made without having ready a solution of adrenaline.

(*b*) *Non-specific Desensitization.*—Experience shows that sensitiveness to a particular allergen may be diminished by treatment not only with this allergen, but also with any other substance to which the patient may be sensitive. When skin reactions are obtained with many different proteins, good results may be expected by treatment with any one of them. We may speak of this as non-specific desensitization—though it is *possible* that we are really using the specific allergen which happens to be a common component of many different substances. Professor van Leeuwen found that the majority of asthmatics were sensitive to old tuberculin. Deciding that it was therefore rational to attempt non-specific desensitization by repeated injections of small and gradually increasing quantities of old tuberculin, he proceeded to carry out this treatment in a large number of cases, and has reported striking success. The method has been used to some extent in this country, and a recent report by T. M. Ling[4] shows that results in children are encouraging.

Briefly the method is as follows: a series of decimal dilutions of old tuberculin is needed, conveniently put up in rubber-capped vaccine bottles—namely, 1 in 100, 1,000, 10,000, 100,000, and 1,000,000. The possibility of active *tuberculosis* is excluded as far as possible. A scratch skin test with pure old tuberculin is then performed, and the size of the initial dose is judged by the results. If there is a very *intense reaction*, the first dose should be 0.1 c.cm. of the 1 in 1,000,000 dilution. With a moderate reaction 0.5 c.cm. of this dilution may be given, and with a negative reaction 0.1 c.cm. of 1 in 100,000. Injections are given twice a week, each dose being increased by 0.1 c.cm.; after about four months the interval is increased to one week, and later, for the last four months of treatment, to two weeks. Treatment must be continued for a year or longer. When definite improvement seems to have been achieved, no further increase in the dose is made.

We are able to report on nine cases treated by this method during the last twelve to eighteen months at the East London Hospital for Children, Shadwell. The results have convinced us that in old tuberculin we have a most valuable ally in the treatment of asthma in children. The mothers have brought their children with striking regularity. They are in no sort of doubt that marked improvement has occurred during the course of treatment. An early improvement in the child's general condition is especially noticeable. We may add that a point which seems to throw some doubt on the rationale of this treatment is that we have not seen a positive skin reaction with old tuberculin in any of our cases.

Eight of our cases are boys, one a girl. The most striking successes are Nos. 2, 5, 7, and 8 of our series.

Case 2 is a boy, aged 6 years, who had had attacks of asthma every two to three weeks in the winter months, and at rather longer intervals in the summer, for four years, and who, for a period of about two months shortly before tuberculin treatment was started, was having attacks almost every night. Eighteen months' treatment by the usual methods produced no improvement. He has been treated for one year by injections of tuberculin, and during that time has had only three attacks of asthma.

Case 5 is a boy, aged 8 years, who for about four years had suffered from asthmatic attacks at roughly three weeks' interval. During sixteen months of treatment by the usual methods he had nineteen attacks. During the following twelve months he was treated with tuberculin, and had only five slight attacks.

Case 7, a girl, aged 10 years, had suffered from asthma for about 5 years, attacks occurring at roughly monthly intervals. During 10 months of treatment by the usual methods, and with peptone injections in addition, she had twelve attacks. This was followed by tuberculin treatment, which has been given now for seven months; during this time she has had only three slight attacks.

Case 8 is even more striking, for no attacks whatever have occurred during six months' treatment in a child who was having them at four to six weekly intervals.

Cases 4 and 6 of our series show a slight improvement only—not strikingly different from that obtainable by the usual methods. Cases 1, 3, and 9 are improved, but to an even less degree.

We feel confident in saying that six out of our nine cases have derived considerable benefit from tuberculin injections, and that this is a method which might with advantage be used much more extensively in this country.

THE USE OF EPHEDRINE IN ASTHMA AND WHOOPING-COUGH.

BY

H. HAMILTON STEWART, B.A., M.B., B.CHIR.,

LATE CLINICAL ASSISTANT IN THE CHILDREN'S DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE introduction of ephedrine into the realm of therapeutics has not received the attention in the English literature which it merits. The main facts as at present known of its therapeutic and pharmacological action are as follows:

1. The pharmacological action and chemical structure resemble those of adrenaline.

2. The salts of ephedrine, the hydrochloride and the sulphate, are remarkably stable, and solutions of them can be boiled without any decomposition or loss of activity. They are effective whether given orally, hypodermically, intramuscularly, intravenously, or [illegible]

3. Ephedrine raises the systolic blood pressure. Although it acts more slowly and less completely than adrenaline, yet its action is more prolonged.

4. In animals ephedrine causes contraction of the uterine musculature.[1] It thus differs from adrenaline in this respect.

5. Spasm of the bronchi, not only induced experimentally in animals, but also occurring in asthma, is relieved by ephedrine.

6. Locally the drug acts as a mydriatic[2] and blanches mucous membranes, as those of the nose and pharynx.[3]

7. Given in large doses to animals, its action resembles that of adrenaline in stimulating the release of glycogen from the liver, thus raising the blood sugar.[4] I have found, however, that therapeutic doses of 1/2 grain to 2 grains do not raise the blood sugar level in the normal or diabetic subject.

8. Its clinical application in internal medicine has been extremely wide, but the best results have been obtained in asthma, hay fever, and whooping-cough.

The results reported in this paper have been obtained as a result of treatment of cases of asthma and whooping-cough.

BRONCHIAL ASTHMA.

Nineteen cases of asthma, in patients of various ages, were treated with ephedrine hydrochloride. They may be divided into two groups according to whether they were suffering from (*a*) acute attacks of pure asthma, or (*b*) asthma complicated by bronchitis and emphysema. The majority of these patients had at least one attack per diem, and were in a persistently wheezy condition.

The scale of dosage of ephedrine hydrochloride which was found most satisfactory was: adult, 1/4 to 1 grain; 1 to 5 years, 1/6 grain. The drug was given to adults in tablet form, and to children it was prescribed along with 10 minims of glycerin and chloroform water to the drachm. It is not advisable to give a larger dose than 1 grain, because toxic symptoms are more liable to occur, and, moreover, larger doses do not exert any more beneficial action. Some patients have an idiosyncrasy to the drug, and even 1/2 grain may produce toxic symptoms.

The adult patients of the first group, when seen for the first time in an attack, were given 1/2 grain of ephedrine orally or subcutaneously. When complete relief was obtained it followed oral administration in twenty to forty minutes, and hypodermic injection in ten minutes. Relief is sudden, and occurs simultaneously with the rise in systolic blood pressure, except in those few cases in which the blood pressure is initially high, when it remains unchanged. Oral administration was usually adopted, but in severe cases subcutaneous injection was resorted to occasionally. When the diagnosis and absence of idiosyncrasy were established the patient was instructed to take the drug by the mouth immediately an attack was imminent. In this way attacks were often aborted. In cases of nocturnal attacks the patients received the drug orally just before retiring for the night. They were encouraged to retire after 11 p.m. and forbidden to take any food after 7.30. An undisturbed night usually followed. In those cases in which an attack occurred in spite of the drug a further 1/2-grain dose was taken immediately on waking. This successfully aborted the attack. Eventually it was found that the one dose of 1/2 grain taken on retiring ensured an undisturbed sleep. Unless the nocturnal attacks are frequent it is not advisable to give the drug every night as a prophylactic, but rather to administer it when the attack occurs. In this way any tendency to the development of tolerance is obviated.

Patients in the second group, in whom several attacks occurred during the day, received the drug orally two to four times daily. A very important point in the oral administration of ephedrine is that the drug must be given at least thirty minutes before a meal if an optimum action is to be obtained. In this way one ensures as far as possible that the drug is taken on an empty stomach, and that complete absorption has occurred before food is taken. Thus, if ephedrine is to be given twice a day to an asthmatic or to a child suffering from pertussis, it must be taken at least thirty minutes before breakfast and just before going to bed. The last meal should be taken at least three hours before the patient retires for the night. The results obtained on using this plan were:

GROUP I (10 cases).

Great relief	7
Relief, but toxic symptoms prevented use	1
Failure	2

GROUP II (9 cases).

Number of attacks decreased	4
Period of fewer attacks followed by failure	2
Failure due to toxic symptoms	1
Complete failure	2

The following classification of these cases has been obtained as a result of the study of the history, clinical condition, and severity of the attacks.

GROUP I.	Results of Treatment.
Short history of pure asthmatic attacks, mild or moderately severe	Complete relief.
Long history of pure asthmatic attacks, mild or moderately severe, and with over a week between attacks	Successful.
Severe attacks	Complete failure.

GROUP II.	
Complicated asthma with frequent mild and moderate attacks	Some success.
Complicated asthma with severe attacks	Failure.
Complicated asthma, if tolerance develops	Failure.

One dose of ephedrine gives relief from asthmatic symptoms for three to six hours, but its effect on the systolic blood pressure is shorter. Toxic symptoms occasionally occurred. Palpitation was the commonest, occurring in three cases, headache in two cases, and insomnia in two cases. They were usually slight, but two patients refused to take the drug because of the discomfort. Some degree of tolerance often occurs in cases receiving ephedrine three to four times daily. In two cases the drug failed to give any relief after three weeks' treatment. No cumulative effect of the drug was observed.

PERTUSSIS.

Twenty cases of whooping-cough in the paroxysmal stage were treated with ephedrine hydrochloride. The following points were ascertained before treatment was commenced: (1) the paroxysmal stage had not been present for more than one week; (2) all other drugs were withheld; (3) severe bronchitis was absent.

The success or otherwise of the drug had to be judged by the report of the parents. They were instructed to notice and record (*a*) the number of paroxysms of coughing occurring, particularly at night, and their severity; (*b*) the frequency of vomiting; and (*c*) the number of times the child was heard to whoop. The cases were seen on an average every three days.

The scale of dosage used, according to age, was: Over 5 years, 1/4 to 1/2 grain; 1 to 5 years, 1/6 grain; 6 to 12 months, 1/8 grain; and under 6 months, 1/12 grain. Due regard was paid to the weight of the child. The drug was prescribed with 20 minims of glycerin, and chloroform water to the drachm, and given one to three times a day according to the severity of the case. The same precautions in administration were observed as in the treatment of asthma.

As a result of treatment of these cases it was found that ephedrine gave considerable relief to cases of mild and moderate severity, but in very severe cases it appeared to have no more value than any other remedy given internally. Only in the severe cases, in which ephedrine alone had failed to produce any marked relief, was any other drug administered along with ephedrine. In these cases the following prescription was used:

	According to age
℞ Ephedrine hydrochloride	gr. 5
Tinct. belladonnae	m 5
Vin. ipecac.	m 30
Syr. balsam tolu	ad 1 drachm
Aq. chloroform.	

Belladonna and expectorants, although by themselves practically useless in any case of whooping-cough, if given in conjunction with ephedrine enhance its action. It was found that in these severe cases the mixture gave slightly more relief than ephedrine alone. The beneficial action of the drug is first made evident by the paroxysms of coughing becoming shorter and less severe. Later, with the shortening of the paroxysms, the whoop and vomiting become less frequent. Finally, in successful cases, the child is left with a cough which in no way resembles the violent one of pertussis. It must be stressed, however, that although the violent cough, whoop, and vomiting are relieved, the disease, as shown by malaise, irritability, sweating, etc., continues. No definite toxic symptoms were observed with the dosage used, though sweating was perhaps a little more marked.

CONCLUSIONS.

1. Ephedrine has a definite beneficial effect on moderate attacks of asthma, their number and severity being diminished or even completely aborted.

2. It has no effect on severe attacks of either simple or complicated asthma.

3. Its effect in pertussis is to relieve the violent cough, the whoop, and vomiting, in mild or moderate cases. In severe cases there is no effect at all. The progress of the infection is not influenced, the relief being limited to the mechanical factor.

4. Ephedrine appears to act by relieving the local spasm in the broncho-constrictors. This spasm is produced by the irritant effect of the tough mucus on the mucous membrane, made hypersensitive by the toxins of *B. pertussis*. By relief of this spasm the irritant mucus can be removed without the violent expiratory efforts or coughs which are usually necessary. The paroxysms are thus made shorter and less severe, and hence in favourable cases the whooping and vomiting disappear. Belladonna paralyses the broncho-constrictors, and thus aids the action of ephedrine, which stimulates the broncho-dilators. If belladonna be given with ephedrine it is necessary to antagonize the "drying effect on the secretion" of the former drug by giving an expectorant. In bringing about this effect ephedrine in no way influences the course of the infection, but simply relieves the mechanical difficulty of removing the secretion and hence minimizes the exhausting efforts on the part of the child.

[Since this article was written a further 10 cases of asthma and 15 cases of pertussis have been treated with ephedrine. Similar results were obtained to those described.]

I am indebted to Dr. Jewsbury for permission to publish my results on many of the cases.

A NOTE ON A SYMPTOMATIC TREATMENT OF ASTHMA.

BY

A. T. TODD, M.B.ED., M.R.C.P.LOND.,

HONORARY ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY; LECTURER IN PATHOLOGY, BRISTOL UNIVERSITY.

A FEW short notes on a symptomatic treatment of asthma which has been in use for over four years, and has given consistently good results, may be of interest and possibly of value to others. Accurate figures of the number of patients treated are quite unobtainable, for the majority have been out-patients, and the records are practically impossible to collect. It is estimated that at least three hundred cases have been treated, and only two have shown so little improvement that admission became necessary.

This "system" is not intended to be employed alone, except in asthma of children; in them it has given good results, and in a fair proportion there have been long intervals of freedom from symptoms. In adults the treatment is usually associated with some form of radiotherapy—either *x*-radiation of thorax or spleen, or ultra-violet radiation of the surface of the trunk; or it has been combined with some form of specific or non-specific protein therapy. As this article is not concerned with the whole treatment of asthma, these associated treatments will not be discussed further. A sufficiently large proportion of the cases have been treated solely by this method to convince me that it is of value.

Before starting treatment various etiological factors are inquired into, and removed when possible. Most attention is given to the contents of the bedroom in cases with nocturnal incidence, and to clothing, occupation, and diet of the cases with variable or diurnal attacks. All are advised to take a light supper or dinner and to attend to the common rules of hygiene. In view of the known clinical and experimental relationship of asthma to lesions of the nasopharynx, this is carefully examined and treated if necessary.

This series contains a number of cases of hay asthma and hay fever; both have responded well. The calcium mixture should be administered for about six weeks before the attack is due. The calcium mixture has been altered many times, in attempts to make it more palatable and stable; we have not been able to better the formula now published. It is the camphor which causes most trouble; many people are susceptible to it and develop nausea or syncopal feelings. The camphor may be omitted in cold weather, but in summer the mixture decomposes in a few days unless camphor is present. The calcium mixture contains:

Albuminate of calcium chloride	15 grains
Simple syrup	15 minims
Water	1 ounce

The dose of albuminate is in terms of calcium chloride.

One ounce is a full dose. To this amount is added one-third of a minim of liquor atropinae (*B.P.*). It is given thrice daily for about two weeks and the result is watched. Then the amount of atropine is increased or diminished to that which gives definite, but slight, dryness of the mouth. It is found that it is necessary to reach the lower level of toxicity to obtain alleviation with atropine. Children are given a slightly smaller dose; it is well known that children stand atropine well.

It is not so easy to dispense this mixture as might be thought; it is very much better to make it in bulk, but the addition of the atropine should be reserved until the mixture is issued. The best method for making the albuminate above mentioned is as follows:

Take the whites of seven fresh eggs, add an equal amount of distilled water and 25 grains of powdered camphor. Shake and let stand for two hours or so. Strain through muslin. Dilute to one pint with distilled water and then add 50 ounces of 1 in 3 aqueous solution of calcium chloride. Filter, and, if necessary, make up the volume to 50 ounces.

The dose is 1/2 to 1 fluid ounce, taken thrice daily, after meals. Many patients find that it is less unpleasant if taken in milk, others do not agree. It certainly is so unpleasant that the patients would not go on with it unless there was some decidedly good result. After some weeks of it most of the patients appear to acquire some tolerance and a few even get to like it. A strong peppermint immediately before drinking the mixture is useful. It should be taken regularly, even if the attacks cease, and it should be continued for at least a month after the last attack.

This mixture is used a good deal locally in other conditions in which calcium medication is necessary. It has been found of use in the related conditions—angio-neurotic oedema, urticaria, eczema, and erythema pernio. In these it should be associated with administration of ostelin and parathyroid extract. For some years Messrs. Ferris and Co. of Bristol have manufactured it for private patients; it is called Mist. calci chlor. (alb.) locally, for ease of prescribing.

The second part of the treatment is the administration of the caffeine mixture. This is given in drachm doses at the onset of symptoms, or before the onset when possible. In the event of regular nocturnal attacks a dose is taken before going to bed, and the bottle is kept at the bedside in order that another dose can be taken as soon as any symptom appears. The irregular cases carry a small flask of it about with them. It is quite safe to give several doses in twenty-four hours. This caffeine mixture is called "caffneine" locally, again for ease of prescribing, and has been manufactured by Messrs. Ferris for some years. It contains:

Caffeine sodium iodide	5 grains
Sodium iodide	5 grains
Dilute hydriodic acid (*B.P.*)	5 minims
Decoction of coffee	50 minims
Water	to 1 drachm

The decoction of coffee is made in the usual way with 3 ounces of fresh coffee powder to one pint of water. This is filtered and the three iodides are added.

Before being issued for use 1/4 to 1/2 grain of ephedrine hydrochloride is added to each dose. This has been done for over a year; but the "caffneine" as issued by Messrs. Ferris at the present time does not contain ephedrine.

After two years of experience of ephedrine it is found that not more than 1½ grains should be administered in a day, otherwise unpleasant gastric and circulatory symptoms will be frequent. Children require a proportionately smaller amount.

Discussion of the Mode of Action.

This basal method is not purely empirical and the selection of the ingredients is not fortuitous. It is admitted freely that an exact explanation of the mode of action will have to wait until our knowledge of pharmacology is bettered. In brief, the actions appear to be as follows. Calcium may make up the deficiency of this element, which is usually found in asthma. The defect may be a part cause of the spasm and irritability of the bronchial muscles. It should act in depressing vagotonia, if this be present. It appears to be rather intimately linked with several pleuro-pulmonary disorders. It should reduce vascular permeability. Atropine is too well known to require discussion. Ephedrine has the same actions as adrenaline, but is effectively absorbed from the alimentary canal. Its effects are usually discernible about thirty minutes after ingestion; at least, this is so in cases of colic, in which it is of use also. It should reduce spasm of the bronchial muscles. It should reduce vagotonia, if present. Caffeine is difficult to account for, although it has enjoyed a reputation in asthma for years. Theoretically it should not be of use, for it acts in the opposite direction to ephedrine and adrenaline;[1 2] the latter stimulate the sympathetic side of the vegetative system, the former paralyses it. Caffeine also causes increase of muscular irritability, and so is opposed to calcium. It is possible that it acts by its respiratory and circulatory stimulation. The iodides probably act as expectorants; but in part they may stimulate the sympathetic side indirectly.

It has been admitted that this explanation is scanty and incomplete, but a full attempt would take up much space and still be indecisive.

I have to thank Mr. A. L. Taylor and the pharmaceutical staff of the Bristol Royal Infirmary for their help in the preparation of these mixtures.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

IMMEDIATE ENUCLEATION FOR THE TREATMENT OF QUINSY.

SINCE 1915 I have performed tonsillectomy in various ways on more than 7,000 patients. As up-to-date journals or instruments were not available, for the first thousand or so I used different methods of enucleation by dissection, and still consider that for speed and sureness of removal finger dissection cannot be beaten. The clinic operator, who guillotines his fifteen or twenty an hour, should always have handy a Collins pile forceps, which is necessary in case, owing to previous operations or rigid muscles in the fauces, the guillotine has failed and the patient is coming round.

While watching the course of cases of quinsy the conviction grew that the disease was in reality a septic cellulitis, which settles down into an abscess only when Nature is winning the battle, and at varying rates of formation of pus. It is an attempt to get rid of an infected foreign body, and we should remove it to hasten cure and prevent future invalidism.

It is like taking off the rotting, useless trapdoor of a cellar which one wishes to empty and disinfect, and happens to be as simple. Acting on this assumption, I have performed over 120 of these operations, and have regretted none. Emboldened by the rapid convalescence, immediate relief from pain and fever, and perfect anatomical results, I have extended the operation, and now usually remove the opposite tonsil as well, and often the post-nasal adenoid tissue when present. I do this only when the clinical picture is one of sepsis being successfully fought and one can trust to the patient's plentiful supply of antibodies to heal the extra raw surfaces.

Usually it is not possible to operate until the third, fourth, or fifth day of the disease. Before the operation one should use heat in every form to aid the defensive forces of the system. Sometimes even then pus has not developed, and only cellular jelly meets the gloved finger. Even this, like pus, makes it easier for one to strip the often buried and adherent fibrous tonsil from its bed, the active inflammation digesting the adhesions to the overlapping anterior pillar and plica triangularis. In order to hasten the period of epithelialization of the raw surface one can leave much of the anterior pillar. But I believe the sole use of the muscle in it is to act as the front handle of the "lemon-squeezer" which is formed by the anterior and posterior pillars of the tonsil bed. The "squeeze" should help to empty the crypts of the tonsil during each act of swallowing, and, by the pain produced by swallowing when the tonsil is congested, prevents us from overeating when chilled or fevered. In sthenic or strumous people, who need much antibody in the system, the anterior pillar overlaps the tonsil very extensively, so that much of the tonsil juice is squeezed into the lymph vessels of the neck, where it can produce further effects in the glands. Hence, when we have removed the tonsil the squeezer muscle is unnecessary, and for a series of about 300 patients I removed the anterior pillars (including my own). The results were good, and the "beds" cleaner and free from the dirty clot which sometimes adheres in deep beds, but owing to the extra time taken during healing I usually spare it now.

The instruments are: (1) thick gloves; (2) tongue clip of towel-clip type; (3) gag (Sydenham's preferably); (4) long straight vulsellum or Lane's tissue forceps (I prefer Mayo's vein-dissecting forceps); (5) long blunt-pointed straight scissors (Mayo); (6) long straight Collins pile forceps, with oval fenestrated ends capable of clamping on to the large juicy tonsil when the upper half is stripped from its bed. One can get nearly all of a "ripe" tonsil free; the final movement with the Collins forceps is one of shoving the tonsil down the throat to peel its lingual tail off. Tags and fringes can be clamped and pulled off with it, and this stops bleeding well.

The position is: head extended, hanging down over the end of the table. The anaesthetic is ethyl chloride sprayed slowly on to a Skinner's mask well wrapped round with Turkish towelling, or, for longer work, atropine and chloroform. I have had some very severe and chronic quinsies to treat.

In one case of five weeks' duration with a history of fifteen previous attacks, a two and a quarter inch styloid process snapped off from the skull and came away attached to the back of the quinsy tonsil. Two cases occurred during pregnancy. One at three months proceeded to full term; another had to be operated upon at full term, and three days later I had to deliver her with forceps for a "deep transverse arrest." She made a perfect recovery.

I have several times operated thus for patients with infectious fevers, including scarlet fever and diphtheria, and for others with otitis media and mastoiditis. In one case there was a large cervical abscess, which, opened first, allowed the patient to breathe through the hole in the neck and the tonsil bed, when allowed to do so. The results were perfect, and no complications occurred. I have seen four patients die from septicaemia without an operation being possible—abscess not attempting to form. After operation two or three cases threatened to develop secondary haemorrhage, but the Collins pile forceps pushed well home over the spot, clamped, and jerked away, caused the elastic recoil and intra-vascular clotting in the coiled-up arteries needed to stop it.

This method never fails in the haemorrhage which sometimes follows the use of a too sharp guillotine, or the bleeding which sometimes comes in an alarming flood a few hours after the use of any of the two-bladed (crushing *plus* cutting) guillotines. In "bleeders" haemoplastic serum can be injected either before (if one has warning) or afterwards when one is caught unaware, *actually under the tonsil bed*. One should begin from above in the palate and travel down in the oedema caused by the serum; this relieves one from the fear of touching one of the vessels in the carotid sheath. This method stops "bleeders" from oozing, practically instantly. For members of the working class, who suffer from quinsy repeatedly, can be induced to have an "interval" operation; and this, when it is performed, seems to me to cause much more pain than an operation undertaken during the quinsy.

Bishop's Stortford. R. A. R. WALLACE, F.R.C.S.

THE GLYCERIN TREATMENT OF PUERPERAL SEPSIS.

DR. REMINGTON HOBBS's method of treating puerperal sepsis by the injection of glycerin into the uterus forms, it is generally agreed, a very valuable addition to our armamentarium in fighting this dreaded disease. It depends on the highly hygroscopic action of the glycerin, which induces an increased flow of serum into the uterus. Two practical difficulties arise; one of these has been, so far as I am aware, overlooked, and the other has been only partially surmounted.

The first difficulty is that glycerin stored in ordinary bottles in a damp climate—Calcutta during the rains affords a good example—absorbs so much moisture from the atmosphere that its hygroscopic action on the uterus must be negligible. This was pointed out to me by Lieut.-Colonel T. C. Boyd, I.M.S., professor of chemistry in the Medical College, Calcutta. I suggest to manufacturers that they should put on the market hermetically sealed glass ampullae, each containing about 20 c.cm. of chemically pure glycerin. I should like to suggest further that the hygroscopic action of the glycerin might be augmented by the addition of anhydrous magnesium sulphate. Three grams of this salt can be added to 20 c.cm. of glycerin without making it too viscid. I have used this preparation recently on two cases of streptococcal infection of the uterus with very gratifying results. The magnesium sulphate is sterilized in a hot air sterilizer at 150° C. for one hour, and added to the glycerin before injection into the uterus.

The second difficulty is the method by which the glycerin is injected into the uterus. If the catheter or tube is passed into the uterus daily, the patient, who is very ill, is subjected to a good deal of disturbance: if the catheter is left in situ, so as not to disturb the patient daily, it is certain to slip out and the glycerin is injected next time merely into the vagina. It is suggested in *The Queen Charlotte's Practice of Obstetrics* that a piece of porous sponge tied to the catheter a little below the eye will keep the catheter in position. I would suggest that the difficulty could be best overcome by a specially made large-sized self-retaining catheter, the outer measurement of the tube being half an inch wide and the flanges on each side being three-fourths of an inch. This would be easily introduced and unlikely to slip out.

Reports of Societies.

EARACHE.

A MEETING of the Medical Society of London was held on February 11th, when DR. J. WALTER CARR, the president, paid a tribute of respect from the chair to the late Dr. de Havilland Hall, who was a Fellow of the Society for fifty-five years and its president in 1903.

DR. H. MORELAND MCCREA introduced a discussion on earache. He said that earache, being a pain, must be considered under the classification of pains—namely, localized, as in otitis media or furunculosis; referred pain, due to lesion of the same nerve area; and transferred pain, of which one of the most striking examples in his experience was in a patient subject to attacks of angina, which always began with a violent earache, the pain being transferred to the ear by some unknown means, probably through interconnecting branches of the vagus. A case of otitis media might be one of the most serious things a surgeon had to undertake, and no stone should be left unturned in diagnosis until this condition had been definitely excluded. He emphasized strongly the need for prompt treatment of any acute suppurative inflammation of the middle ear, and the danger to the permanent hearing, perhaps even to life itself, if such measures were delayed. In differentiating furunculosis there was one helpful point which might be remembered, that the common organism in it was *Staphylococcus aureus*. Minor local causes of earache might be the presence of cerumen in the meatus, or an increase of atmospheric pressure due to blocking of the Eustachian tube by adenoids. The points in examination were: history; constitutional disturbance; condition of the drum, whether bulging or perforated, and accompanied or otherwise by discharge; temperature; state of the lymphatic glands and the bone; and deafness. If there was no local cause for earache, the next thing to do was to examine the regions from which the pain could be referred or transferred. The salivary glands could cause earache; as a referred pain it might be due to acute tonsillitis, and continue after enucleation of the tonsils; ulceration or erosion of the tongue, again, could bring about constant or intermittent intense pain in the ear. An aching tooth might also be the cause; intense ear pain might be induced by a buried wisdom tooth. Disease of the larynx could give rise to intense earache, which might be purely transferred pain. The possibility of the origin of the pain being an early cancer or tuberculous lesion in this area should not be disregarded.

MR. HERBERT TILLEY said that earache was a very deceptive symptom in that the gravity of the causative lesion might have little proportion to the severity of the pain. A furuncle in the meatus, although not endangering life at all, might render life intolerable for three or four days, while an earache which was scarcely more than a bearable discomfort might be the only subjective symptom of retained sepsis in close proximity to the temporal meninges. Dealing with intrinsic causes, Mr. Tilley first touched on foreign bodies, such as a pea or some vegetable grain, in a child's ear, sometimes possible of expulsion by gentle syringing, otherwise, if impacted, requiring removal with a suitably curved probe or hook under a general anaesthetic. A not infrequent foreign body was a foul pledget of wool which the patient had forgotten to remove. Cerumen pressing against the tympanic membrane might cause earache, but more particularly vertigo. Furunculosis, due to staphylococcal inflammation of a hair follicle or sebaceous gland in the epidermic lining of the cartilaginous portion of the meatus, sometimes resulted in intolerable pain. With regard to the differentiation of this condition from mastoiditis Mr. Tilley suggested three points: the hearing would probably be normal in the case of furuncle, whereas in mastoiditis there was likely to be some damage to the middle-ear structures; the movement of the jaw or auricle would accentuate the pain in meatal inflammation, but hardly that caused by mastoiditis; and direct pressure on the oedematous area would not greatly increase the pain of a furuncle, but would accentuate that due to inflammation in the mastoid antrum or cells. Dealing with acute inflammation of the middle-ear cleft, which furnished the physician with most of his cases of severe earache, if the physician satisfied himself that acute inflammation of the intact tympanum was present he should, in the case of a child, make arrangements for a brief general anaesthesia in order that the tympanic membrane might be incised. In the adult local anaesthesia could be used. It was his firm conviction that once the tympanic membrane was acutely inflamed and uniformly congested paracentesis should be performed. A clean and free incision through the posterior half of the drumhead provided immediate drainage for inflammatory products from the tympanum, thereby saving the delicate mechanism of the middle ear from possibly irreparable damage, and perhaps also hindering a spread of infection to the mastoid antrum, its cells, or to important regions in the vicinity. The milder and fugitive forms of earache in children, Mr. Tilley added, should be taken as a note of warning by the thoughtful physician. They almost invariably implied a mild infection of the Eustachian tube and middle ear, and examination of the nasopharynx would frequently reveal that abnormal degree of lymphoid hypertrophy which was called adenoids. In chronic suppurative otorrhoea earache should be regarded as a symptom of arresting significance, because it meant that septic inflammatory products were retained under tension in the middle ear or on its adnexa. In these circumstances, and without the addition of any other local or general symptoms, one would be justified in adopting surgical measures for the free exposure and drainage of a septic focus. Earache might be complained

of in patients suffering from chronic non-suppurative inflammation of the middle-ear cleft which had given rise to the formation of cicatricial changes in the tympanum or of sclerosis of the mastoid bone. In such instances the earache was usually of a dull boring character, as compared with sharp pain of the more acute inflammatory types. With regard to referred earache, Mr. Tilley contented himself with a reference to earache caused by chronic or suppurative inflammation within the sphenoidal sinus and the regions in its neighbourhood.

Sir JAMES DUNDAS-GRANT said that disease in the tonsil was often the cause of earache, but sometimes, when both ear and tonsil showed signs of inflammation, it was difficult to decide which was the cause. If one could anaesthetize the tonsil and thereby remove the pain in the ear it was a reasonable possibility that the pain was a reflected one from the tonsil. In the examination of the ear of a small child it was useful to tilt the head and pull the floor of the meatus downwards (not upwards as in the adult) and backwards, which gave an astonishingly good view of the tympanic membrane.

Mr. THEODORE JUST referred to the curious prejudice in some quarters against the use by the aural surgeon of an electrical auroscope. He considered it wrong to teach the student to discount the use of electrical weapons in the examination of the ear, and he emphasized the need for the best illumination possible. He considered also as unjustified the prejudice against the opening up of the mastoid on suspicion of mastoiditis. After all, the danger of opening up a doubtful mastoid was no greater than that of opening up a doubtful appendix case, which was undertaken without any question.

Mr. HAMBLIN THOMAS said that sometimes in infants a minute streptococcal infection of the skin behind the ear was found, accompanied by a good deal of pain. Pain was also caused in the ear by the presence of wax which had been there for a long time and had come to exert a certain pressure, and the skin underneath it had become atrophic. Even after the wax was removed pain might continue for some time. In the treatment of the pain carbolic acid drops and glycerin were commonly given. This might relieve the pain for a few days, but after a time the carbolic acid removed the superficial layers of the epithelium, with consequent pain in the ear again. Some people were sensitive to the crystals of boric acid, which was often used in cleaning out ears. Short stabbing pains in the ear occurred in people with arterio-sclerosis and high blood pressure.

Mr. ERIC STEELER agreed with Mr. Tilley as to the importance of performing a paracentesis once the tympanic membrane was acutely inflamed. It was far safer to open the drum than to let it go on to spontaneous rupture.

Mr. TILLEY, replying to a question as to how often he had seen earache as a referred trouble from sphenoidal suppuration, said that he had only seen two cases in thirty years, but they were quite definite and unmistakable.

EARLY DIAGNOSIS IN SPINAL INJURIES.

AT a joint meeting of the War Section and the Section of Surgery of the Royal Society of Medicine on February 6th a discussion took place on the need for early diagnosis in the treatment of spinal injuries. Sir HOLBURT WARING presided.

Group-Captain H. V. WELLS, who spoke from the point of view of fractures due to aeroplane crashes, referred to those less obvious cases in which the body of a vertebra was fractured without any immediate or grave involvement of the spinal cord or spinal nerves. There were "missed" cases in which, weeks or months after the injury, a spinal curvature or a definite neuritis showing involvement of the spinal nerves was discovered. After an aeroplane accident, judged not to have been of a serious nature, the medical officer merely recording a bruising or straining of the muscles of the back, the patient might be rested in bed for a few days, treated by massage, and then sent back to his duty; then, weeks later, he would seek medical advice for shooting pains or inability properly to straighten his back, and a skiagram would disclose an undoubted fracture and damage beyond rectification except by extreme measures. Fractures of the upper part of the spine were brought about by the spine being forcibly bent upon itself, the head being forced forward upon the curved upper spine, when the position about the second or third dorsal vertebra probably received the maximum compression. Fractures of the lower region were brought about by the weight of the head and chest, supported on the lumbar spine at the moment of impact, being reinforced by the rebound transmitted through the lower limbs. The particular type of fracture concerned in that discussion was a compression fracture involving the vertebral body only. The obvious way to settle any doubt was to radiograph the spine in all such cases. But would the skiagram at this early period show anything definite? There was no appreciable displacement, the crushed vertebra had come back into position near to its normal outline, and although the bony outline might be a little suspicious, one was left still in doubt. The only things on which the medical officer could rely were the history of the accident (which gave some indication as to the likely damage); the persistence of pain, not in itself a sure guide; and the skiagram, which could give little help where there was no marked displacement. Many patients who had been involved in flying accidents had subsequently suffered for varying periods with definite pain in the lumbar region, with maximum tenderness located over one or other lumbar vertebrae, but x-ray examination failed to reveal any signs of a bony lesion. All these patients had subsequently recovered without any residual symptoms, and it was suggested that in these cases the lumbar vertebrae suffered from the effects of compression, with severe bruising, without actual fracture. Possibly severe compression might give rise to some lesion of the bone, with or without definite fracture, resulting in subsequent absorption of bony tissue. From the skiagram there appeared to be no guiding factor to enable the medical officer to say whether the lesion was minor or major. The right policy would seem to be that any patient who complained of pain in the back after a serious accident should invariably be treated as a potential case of fracture, but to lay this down as a hard-and-fast rule would involve the loss of a considerable number of man-hours purely as a matter of safeguard.

Sir PERCY SARGENT said that since the war the cases of spinal injury which he had seen had been mostly due to two common causes—namely, colliery accidents and hunting accidents. In the former the injury was usually caused by the fall of a mass of coal or stone on the back while the man was in a stooping posture; in hunting accidents hyperflexion of the spine probably played the chief part. When the force was extreme, fracture resulted. He limited his remarks, however, to those cases in which no conspicuous damage was done, though the patient might suffer considerable disability later on. The great necessity was to make up one's mind at an early date as to the right line of treatment in these cases of apparently minor injury. Diagnosis and prognosis were notoriously difficult in such cases, and it was only wise to impose upon these patients a probationary period, not necessarily of rest, certainly not of rest alone, but of observation and treatment. Systematic neurological examination should always be made and repeated from time to time in case any physical signs turned up at a later period. A good skiagram, lateral as well as antero-posterior, should also be made. The spine which appeared normal radiographically immediately after the accident might, months afterwards, show atrophy and collapse of one or more vertebral bodies. It had been suggested—and was possible—that in these cases some early operative measure might legitimately be employed, but in most the cure of the pain and stiffness and the arrest of the oncoming deformity could be obtained by proper treatment of the muscles. The spine required support from its ligaments and muscles, and by a proper treatment of the muscles he meant such measures as would improve their tone, and perhaps their bulk, but would certainly enable them to deal with the extra strain thrown upon them in consequence of the spinal damage. Such treatment might include massage—though he had no opinion as to that beyond its ability to improve nutrition—and also electrical stimulation, by which he meant the production of rhythmically graduated contractions, not the painful tetanic spasm brought about by the strong faradic current

This was a means of toning up the muscles and improving their supporting power. If the contractions were systematically and rhythmically applied the whole treatment had a very far-reaching effect on the condition of the soft parts, the bones, and everything else. It had to be borne in mind in spinal injury, even of a slight degree, that symptoms of pressure on the cord might occur a long time after an injury. Many victims of aeroplane accidents, who showed no obvious signs of spinal injury at the time, might produce evidence of serious later effects such as collapse of vertebral bodies and secondary spinal cord symptoms. The effects on the spinal column might be prevented by proper treatment of the damaged muscles. Possible late effects upon the spinal cord and nerves could not be foreseen, and must be so rare that in this particular connexion they might be disregarded, but with this exception, that patients who showed slight or even transient signs of cord injury must be very carefully watched, in view of the likely development of serious symptoms at a later date.

Air Vice-Marshal DAVID MUNRO remarked that he had never seen a psychological factor in the cases of spinal injury consequent upon flying crashes. He also mentioned that a senior officer in the Air Force got a serious injury in 1915, but had served ever since then without complaint, yet he was now in the hands of an osteopath, who declared that he had symptoms of spinal damage. What was the pathology of these delayed cases? Why did an injury take so long to develop? The only suggestion he had heard was that there was extravasation into the cancellous tissue of the bone.

Surgeon Vice-Admiral A. GASKELL said that the fractured spine, consequent upon sacks of coal falling upon the back, was not uncommon in the navy. The point was how to assess the injury to the spinal column. It was important always to take skiagrams, and here he mentioned that naval hospitals were very fortunate in their x-ray equipment. An autopsy in all fatal air crashes would be of value in studying injuries to the spinal column.

Major J. M. WEDDELL said that in these missed compression fractures very often the trauma was relatively minor. In the late case the man would come up complaining of pain in the back, which was definite and increased by movement. The man held his back rigid, and there was stiffness with possible deformity. If there was not deformity there was still very often irregularity of the spinous processes. The skiagram in the typical case showed a deformed or wedge-shaped vertebra. He did not know at what period localized hyperaesthesia arose; if early it would be a helpful diagnostic symptom.

Dr. BERTRAM SHIRES commented on the fact that in no case brought forward, after a skiagram in the early stages had shown no fracture, had a fracture been discovered. In the late cases it was quite possible that had the spine been x-rayed immediately after the accident the fracture would have been shown. Radiological evidence of fracture might be very slight, but it was recognizable, provided the lateral view were taken.

Dr. MORTON SMART had been impressed by the importance of the muscle factor in keeping the body erect. When an injury to the spine occurred the muscles, which were the first line of defence, must give way, with the result that in all fractures of the spine there was serious injury to the muscles and possibly to the ligaments. In the mild cases of compression of the vertebral body there was no question that if put to bed for a time and kept at rest they made good progress to recovery, but in a short time after getting up a variety of pains in the back was experienced, some of them being referred to the definite area, and some to other parts of the body, the latter being due to muscle strain in trying to take off the pressure from the directly affected part. The muscles in the course of repair became adherent to neighbouring tissues, and pain in the late case was often due to these adhesions. The successes of the osteopath were hereby explained, for he by violent measures loosened the adhesions, and the patients thereupon lost their pain, though the osteopath claimed that the cause was a bone out of position.

Mr. CECIL WAKELEY referred to cases in which the skiagram taken on one side showed fissuring of the vertebra, but nothing of the kind on the other side. Mr. PATERSON ROSS suggested that the primary factor in producing wasting and atrophy was pain. Painful joints would always result in wasting and atrophy of the surrounding muscles. It might be that the severe pain which resulted from the injury produced a great deal of atrophy, leading eventually, with loss of support, to the wedge-shaped vertebrae. Commander PRISTON spoke on the psychological difference noted as between the victims of hunting and of industrial accidents. The former were persons who were accustomed to exercise their muscles, and were not afraid of a little pain, and so broke down their adhesions. In other cases compensation came in and perhaps to some extent destroyed incentive. Sir HOLBART WARING had seen a number of these injuries which, being due to torn ligaments and adhesions following them, were specially amenable to the so-called bone-setter.

Sir PERCY SARGENT, in reply, said that, as regards the pathology of crushed fractures, the actual condition of the bones, and the reason why they were collapsed, were still unknown. There were two or three post-mortem examinations of crushed fractures at an early stage where nothing had been found but the crumbling of cancellous tissue of the bone with haemorrhage into it. It was not explained why such crumbling appeared so long after the original injury.

THE INJECTION TREATMENT OF VARICOSE VEINS.

AT a meeting of the Liverpool Medical Institution on January 10th a discussion on the injection treatment of varicose veins was opened by Dr. STUART MCAUSLAND.

DR. MCAUSLAND gave an historical review of the Continental and British literature, and cited deficient endocrine stimulation as a primary etiological factor in the formation of varicose veins. From the histological aspect he maintained that the process of vein obliteration by injection was essentially a chemically produced irritation of the endothelium, which caused the formation of a firm clot. This condition, together with the fact, radiographically confirmed, of the downward circulation in varicose veins, and the innumerable clinical successes of Sicard and others without accident, negatived all danger of embolus. Having discussed indications and contraindications he described the technique, and reported results of his own cases, together with after-effects. He concluded that salicylate of soda, and quinine with urethane, were the substances of choice; that patients should rest the limb for twenty minutes after injection; and that the advantages of the method were exactly those of haemorrhoid injections. The treatment was essentially ambulatory, nearly painless, and economically cheap; it was more successful than operative excision, smaller radioles being reached and recurrence being less liable. The treatment, moreover, avoided the risks of general anaesthesia and post-operative embolus.

Mr. H. F. WOOLFENDEN emphasized the apparent safety of the injection treatment as regards the risks of pulmonary embolus due to the firm character of the thrombus formed, the thrombosis being secondary to the chemical endophlebitis and resembling the tough fibrinous thrombus met with in aneurysm. The convenience of the treatment from the patient's point of view was undoubted, and the permanence of the cure seemed to be as good, if not better, than after operation. There were certain disadvantages of the treatment to be considered. The first was pain, which at times occurred; it was sometimes met with at the time of injection when sodium salicylate was used, but for some days afterwards patients complained at times of pain and tenderness in the leg. This might possibly be due to a part of the injection being outside the vein, or to a leak back at the puncture hole in the vein, but it also occurred when the injection was undoubtedly in the vein, and was due to an excessive reaction causing periphlebitis. This excessive reaction had four possible causes: (1) the solution being too strong, (2) stagnation in the vein, (3) thinness of the vein wall, and (4) idiosyncrasy of the vein. There was also the possibility of errors in technique causing slough formation by the injection outside the vein. This should not occur, but unfortunately it did occasionally happen.

The advantages and disadvantages of quinine, sodium salicylate, and sodium chloride were discussed. Quinine and urethane were most suitable for the peripheral injection of small and moderate-sized veins, but sodium salicylate and sodium chloride given by Colt's technique were excellent for large varices involving the long saphenous system, on account of the quickness of the cure. The importance of bandaging the leg after injection was pointed out so that the formation of large bulky clots could be avoided.

Mr. J. B. OLDHAM said that before recommending any new form of treatment it was necessary that it should be safe and efficacious. He was certain that these postulates were fulfilled by the injection treatment of varicose veins. On the question of safety the sceptics advanced as objections the risk of general toxic symptoms, of local complications, and of pulmonary embolism. Several examples of severe quininism, following excessive doses, were mentioned, but the speaker found that all these risks could be obviated by giving a very small initial dose (1/2 to 1 c.cm.) to test the patient's susceptibility; by not giving more than 7 to 8 c.cm. at one sitting; and by keeping the limb at rest for half an hour after injection. Mention was made of Sicard's experimental proof that solutions injected in varices remained there if the limb was kept at rest, but quickly entered the general circulation on active movement; a similar personal observation following injection of methylene blue was related. Local necrosis was almost always the result of the solution entering the subcutaneous tissues—an error in technique—but occasionally, as Mr. Woolfenden had mentioned, necrosis followed what apparently had been a perfect injection. Embolism was an ever-present theoretical possibility, but the practical clinical evidence of many hundreds of thousands of injections without a fatality—no case of fatal embolism following a sodium salicylate or quinine injection has been reported—was more than sufficient to outweigh this hypothetical danger. In spite of the unlikelihood of embolism these precautions were advocated: (1) the patient should not move for half an hour after injection; (2) absolutely aseptic technique; (3) if possible, avoidance of excessive muscular activity for three or four weeks after completion of treatment. The advantages over the operative methods were enumerated, and it was pointed out that one fatal case of embolism happened in every 700 or 800 major operations. The speaker thought that a tourniquet was helpful, and that injections should be given with the patient lying down; he mentioned that quite independently he had come to the same conclusion as Mr. Woolfenden as to the great advantages of supporting the veins with a bandage for a few days after injection. In cases with a positive Trendelenburg sign good results could often be obtained by a single injection made as near the proximal end as possible, the consequent fibrosis being equivalent to the old Trendelenburg operation, and protecting the distal veins from the passive downward reflux of blood.

HAEMORRHAGE AFTER THE MENOPAUSE.

At a meeting of the North of England Obstetrical and Gynaecological Society on January 25th, with the president, Dr. GORDON FITZGERALD (Manchester), in the chair, Dr. S. B. HERD (Liverpool) read a paper on post-menopausal haemorrhage.

Dr. Herd said he had recently been confronted with several cases in which haemorrhage after the menopause had been the only symptom and there had been no gross physical signs. One patient was a single woman with a recent history of slight bleeding considerably after the menopause; no pelvic abnormality could be detected on ordinary examination. Preliminary examination under anaesthesia with diagnostic curetting had been objected to by her private doctor for three reasons: entailment of the risk of two anaesthetizations; the danger of missing an early growth even after careful scraping; and the possibility of disseminating growth, if present, by manipulation. On investigating this case Dr. Herd had found a four-inch uterine cavity and slight irregularity at the fundus; friable material had been removed by the curette, so he had performed total hysterectomy for what had proved to be an early carcinoma of the body of the uterus. On investigating the literature he had found many conflicting views. Dougal had classified these cases in two groups—namely, those with and those without gross physical signs. Muret in 1927 had analysed 312 cases; he had found 25 per cent. to be malignant, the cervix and corpus uteri being equally affected. In the latter cases none had been obvious before curetting. Muret had also noted that 19 per cent. of his cases were due to ulceration associated with prolapse, and that 8 per cent. were due to polypi and senile endometritis. In only three cases had Muret found no positive result after careful examination and curettage. Lahen had described four cases of post-menopausal bleeding where operation had revealed primary ovarian carcinoma and where the endometrium was of the active pre-menopausal type. He had suggested that the malignant growth had in some way revived ovarian function. In two articles in the *British Medical Journal* in 1926 and 1927 Fletcher Shaw had discussed post-menopausal bleeding and had stated that malignant degeneration in fibroids might be overlooked by curettage. Russell Andrews had mentioned a case of post-menopausal bleeding due to rupture of a vein in the capsule of a fibroid. Wallin, in the *Journal of the American Medical Association*, had reported a case due to hypothyroidism.

Dr. Herd said he had analysed 82 cases of uterine haemorrhage occurring after the menopause, and had found the following conditions:

Carcinoma cervicis	40 (43%)
Adenomatous polypi	15 (16%)
Carcinoma corporis uteri	12 (13%)
Fibromyoma uteri	6 (7%)
Pyometra	4
Simple ovarian cyst	3
Cervical erosion	3
Sarcoma corporis uteri	2
Prolapse with pessary	2
Twisted ovarian cyst	1
Primary ovarian carcinoma	1
Secondary ovarian carcinoma	1

In all these cases some local cause had been found on careful examination. In 72 cases there had been obvious physical signs, but in 20 cases the cause had not been so apparent. There was nothing outstanding about the cases of cervical carcinoma except that only three had been inoperable. This high operability rate was in all probability due to the fact that the growth had been of a slow-growing type. Of the 15 cases of adenomatous polypi none had presented difficulty in diagnosis, and in no instance had abdominal section been found necessary. Submucous tumours had been present in all 6 cases of fibromyomata, and in 2 of these cases necrobiotic change had been found. The site of haemorrhage in all had been in the capsule of the tumour. In those cases where haemorrhage had been due to tumours in the vicinity of the uterus a mechanical cause had been suggested by two cases; in the first a cystadenoma with twisted pedicle had been found and its removal had been followed by cessation of bleeding; in the second, after removal of a primary ovarian carcinoma the bleeding ceased and had not since recurred. In conclusion Dr. Herd emphasized the fact that in all cases in which the diagnosis had not been obvious and in which malignancy had been subsequently found, this diagnosis of malignancy had always been established by curetting, and in no malignant case had the diagnosis been missed by the curette.

The PRESIDENT said that personally in such cases he was always particularly careful to exclude carcinoma of the cervix in parous women, and carcinoma of the body of the uterus in nulliparous women. He thought that senile endometritis was very rare; it was a diagnosis he always avoided. He had recently seen a case of haemorrhage six months' duration in a woman, aged 66, twenty-six years after the menopause. No abnormality had been discovered on curetting the cervix and body of the uterus, but, not being satisfied, he had performed laparotomy and had found a small primary carcinoma of the Fallopian tube.

Dr. ARCHIBALD DONALD (Manchester) suggested that more stress might have been laid on the question of polypi as

a cause of post-menopausal haemorrhage. He thought that the proportion of fibromyomata would have been larger if fibroid polypi had been included in this group. Fibromyomata frequently caused bleeding after the menopause owing to atrophy of the capsule and the consequent liability of the vessels to rupture. He had seen very few cases of senile endometritis, and most of these were really cases of senile pyometra. When post-menopausal bleeding was associated with an ovarian cyst and a twisted pedicle he thought the haemorrhage was due to back pressure.

Dr. J. W. BRIDE (Manchester) recalled a case in a woman, aged 60, who had been married six months. Examination had revealed a polypus growing from the cervix and nothing further had been found on curettage. The bleeding continued, and hysterectomy, performed later, revealed carcinoma of the body of the uterus.

Dr. FLETCHER SHAW (Manchester) thought that many medical practitioners were still apt to overlook the seriousness of post-menopausal bleeding. He had seen a case recently where a urethral caruncle had been present; he had thought that this was the cause of the bleeding. However, he had curetted the uterine cavity, as was his custom in such cases, and had found carcinoma in the body of the uterus. He was rather at a loss to understand why the endometrium should suddenly become rejuvenated and produce polypi. He was surprised at the small proportion of fibromyomata in Dr. Herd's figures, as he had seen many cases of post-menopausal haemorrhage following changes in fibroids.

Dr. F. H. LACEY (Manchester) emphasized the necessity for curetting in all these cases. It was dangerous to assume that a caruncle or polypus, if present, was the cause of the haemorrhage. He had known cases where, on this assumption, carcinoma of the body of the uterus had been missed. Dr. LEITH MURRAY (Liverpool) agreed with Dr. Herd in regard to the low proportion of fibromyomata causing post-menopausal bleeding. In his own series he had found that only 3 per cent. of cases were due to uncomplicated fibromyomata. He was strongly of opinion that much could be done to bring the danger of such bleeding to the notice of the public by instruction of midwives. Dr. KING (Sheffield) disagreed with curetting in these cases. He believed in performing vaginal hysterectomy at once. He was also of opinion that post-menopausal polypi were evidence of a pre-malignant condition. Dr. GOUGH (Leeds) did not consider that in the cases due to twisting of the pedicle of an ovarian cyst the cause of the bleeding was mechanical. He had seen haemorrhage in very small ovarian tumours, and thought it was possibly due to a hormone produced in the connective tissue of the ovary, as no lutein tissue was present. Dr. HERD, in reply, said that he also thought there must be some other cause than the mechanical theory in such cases.

Spontaneous Uterine Rupture.

Dr. J. W. BRIDE (Manchester) showed a specimen of spontaneous rupture of the uterus about the fourth month of pregnancy. The patient was a primigravida, married four and a half years, and very anxious to have a child. There was no question of previous operation at any time, or of accident. The specimen consisted of the uterus removed by subtotal hysterectomy and enlarged to the size of a four or five months' pregnancy, and behind and above the left cornu could be seen a large gaping tear, through which protruded placental tissue, the head of the foetus being distinctly seen and felt through the opening. Part of the intact bag of membranes could be seen protruding through the lower pole of the uterus at the level of the internal os. There were some small fibroids in the uterine wall, which measured one-sixteenth to one-eighth of an inch. The symptoms had been those of rupture of an ectopic pregnancy, the patient being critically ill at the time of operation, but making eventually a good recovery. Dr. Bride had come to the conclusion that it was one of those rare cases of pregnancy in an infantile uterus. At the time of operation the uterine walls were uniformly transparent and very thin. There did not appear to be any question of cornual pregnancy or any evidence of hydatidiform disease.

Dr. ARCHIBALD DONALD (Manchester) asked whether the patient had ever been examined bimanually prior to the occurrence of pregnancy, and if so, whether or not the uterus had been found to be of the infantile type. He remembered a case where pregnancy had occurred in an infantile uterus, and where, at the fourth month, the uterine wall, on palpation, had seemed extremely thin. In spite of this the patient had subsequently gone through a normal confinement at full term. Dr. FLETCHER SHAW (Manchester) suggested that the rupture might have been due to a very rare condition—namely, acute sacculation of the uterus during pregnancy. He had had a case of this kind. In Dr. Bride's case there was no history of acute pain at the time when sacculation would have taken place. Dr. LEITH MURRAY (Liverpool) suggested that the presence of leucocytic infiltration of the uterine wall showed that the rupture might have been due to an inflammatory condition. Dr. KING (Sheffield) mentioned a somewhat similar case he had seen in a multipara where spontaneous and fatal rupture had occurred at the sixth month. In the previous confinement the puerperium had been morbid, and on the ninth day, following a secondary post-partum haemorrhage, she had passed what appeared to be a piece of placenta. Microscopic examination had shown it to be a piece of uterine muscle. He suggested that in his case there had been, after the first confinement, haemorrhage into the uterine wall analogous to accidental haemorrhage; this had resulted in a uterine scar, which had ruptured during the next pregnancy.

Dr. BRIDE, in reply, said that his patient had never been examined bimanually before becoming pregnant, so he could not say whether the uterus had been infantile in type. At the time of operation the whole uterine wall was very thin and almost transparent.

WORK OF THE MACKENZIE INSTITUTE.

AT a meeting of the London Association of the Medical Women's Federation, held at the British Medical Association House on January 22nd, with the president, Miss F. HUXLEY, in the chair, a paper was read by Dr. DOROTHY DOUGLAS on the working of the Mackenzie Institute for Clinical Research at St. Andrews.

After briefly outlining the foundation of the Institute, and commenting on the life and work of its great originator, Dr. Douglas went on to explain the aims of the organization. These were principally: (1) to obtain a large series of accurate life-histories of the health of individuals whose circumstances, habits, and, if possible, antecedents were known; and (2) by an intensive and minute study of cases of disease, especially in its early stages, to arrive at a better knowledge of the meaning of symptoms, as opposed to physical signs. Disease states might be divided into two groups: first, those in which there were symptoms only, without physical signs, and therefore only disorder of function; secondly, those in which physical signs could be elicited, and therefore structural change might be postulated. It was always Mackenzie's aim, by an early recognition of the first group, to prevent the occurrence of the second. St. Andrews was chosen as the site for such a research chiefly because it was a very small and somewhat remote town. This made it comparatively easy to follow up patients and to discover facts about their families and circumstances; moreover, it was there possible to keep in touch with individuals over a large number of years, since the population was more or less stationary. For much the same reasons it was decided to staff the Institute entirely from general practitioners of the town, since they would naturally be the first to see the earliest symptoms of disorder. It had since been found practicable to employ, in addition, a full-time pathologist and bacteriologist, a radiologist, and a paediatrist. The services of the general practitioners were entirely voluntary, and the prevalent feeling locally, both among the doctors and the general public, was that the work, besides being part of a most necessary research, acted as a stimulus to thought and discussion, and much increased the interest of the routine of general practice. Many important papers had been published by the Institute since its foundation, and a comprehensive mass of material in the shape of accurate clinical notes of a large number of cases of special interest had been gathered together. This material was available to investigators following out a particular symptom or disease. In conclusion, Dr. Douglas expressed the hope that such unique opportunities for clinical research as were offered at the Institute would be utilized to the full.

Reviews.

VACCINATION WITH LIVING TUBERCLE BACILLI.

PROFESSOR ALBERTO ASCOLI of Milan, in a recent work on vaccination against tuberculosis with living tubercle bacilli,[1] makes an interesting contribution to the problems raised by Calmette and Guérin with their B.C.G. vaccine. Starting with a review of previous work in the immunization of cattle with human tubercle bacilli, in which a tribute is paid to the pioneer work of Angelo Maffucci in this field, and a useful summary is given of the classical experiments of R. Koch, Behring, and others, Ascoli passes on to his own experiments, which are described in considerable detail.

His first experiment was carried out at Stradella in November, 1926, four calves, vaccinated with B.C.G. between April and September, 1925, and three non-vaccinated "controls" each being tested by the intravenous inoculation of 5 mg. of the same virulent culture of bovine tubercle bacilli (Vallée) as had been used by Calmette in his experiments. Unfortunately, septic pneumonia had been prevalent in the stalls in which these calves were accommodated, and several of them had suffered from transitory attacks, though they appeared to have quite recovered at the time of the test inoculation. In the result, all except one vaccinated and one control animal died of septic pneumonia within three weeks of the test dose, a latent pneumonic infection being, as Ascoli believes, reactivated by the shock of the intravenous inoculation. It was found at necropsy that tuberculous lesions coexisted with septic pneumonia in the lungs of the non-vaccinated "controls," whereas the lungs of the vaccinated calves, while pneumonic, were free from tuberculous foci. In the course of bacteriological examinations *B. bovisepticus* was isolated from all these animals. Of the survivors, the control was killed in May, 1927, and the vaccinated calf in January, 1928. Both showed tuberculous lesions, the latter having a subacute tuberculous meningitis.

The Stradella experiment, in fact, was a failure, though it served to emphasize a point to which Ascoli attaches importance—the tendency for inoculations of tubercle bacilli to wake up latent foci of intercurrent bacterial diseases. A more successful attempt was made at Cascinazza in April, 1926, when two vaccinated and two non-vaccinated calves were tested with intravenous inoculations of 5 milligrams of a virulent bovine strain isolated by Ascoli himself. In this experiment both the "controls" went rapidly to the bad, and died early in May, 1926, of generalized tuberculosis. The vaccinated calves, however, remained for many months in good health. The photographs and temperature records illustrating this experiment are striking. In August, 1927, however, one of the vaccinated animals developed cerebral symptoms, was slaughtered, and was found at autopsy to have tuberculous encephalitis, though the lungs were free from visible tubercles. An emulsion of lung tissue, however, inoculated into a guinea-pig led to tuberculosis. The other was still fat and healthy in January, 1928, when it was slaughtered. At autopsy the tracheo-bronchial glands were found enlarged and caseous, and emulsions of their contents, as well as of lung tissue, reproduced tuberculosis in guinea-pigs. The vaccinated animals, then, were not rendered absolutely immune to tuberculosis, but it is clear that they were made "refractory" to a very heavy test infection, and were much more resistant than the controls. Further experiments with calves, in which the test was exposure to close contact with infected cattle, gave results which, in spite of interference through actinomycosis as an intercurrent infection, were, on the whole, in favour of the vaccine. Experiments in goats failed, in one series, through the test dose being too large, and were successful in a further experiment with a smaller test dose, in which, however, only one vaccinated and one control animal were used. In swine good results followed B.C.G. vaccination where the vaccine was given subcutaneously, but experiments with oral administration of the vaccine failed.

On the whole the experiments, though on a small scale, gave results comparable with those obtained in this country and elsewhere. They proved that B.C.G., like other living strains of tubercle bacilli, leads, when given in appropriate doses, to a considerable increase of resistance against subsequent heavy infection with virulent cultures. On the other hand, the experiments suggest that the B.C.G. strain, when grown and used according to the method of Calmette, is innocuous for test animals. Lesions it does produce; and Ascoli gets nearer the truth than Calmette when, instead of asserting that B.C.G. is "non-tuberculigenic," he speaks of it as "tuberculigenic but non-tuberculosigenic." Experiments in the pre-immunization of infants were carried out on a small scale by several medical practitioners working under the general direction of Ascoli himself. The observations, though small in number, are well reported, and it is of interest to note, in several of the *x*-ray photographs reproduced with the text, that vaccinated children, regarded as fairly healthy in other respects, showed definite lung lesions. Out of about 165 children followed up, 18 appear to have died, one admittedly from tuberculosis and many from catarrhal enteritis. Altogether, in spite of the fact that Ascoli regards them as favourable, these tests on infants do not seem to the reviewer to be very convincing. In fact, while the author concludes in favour of B.C.G. vaccine, the impression left on the mind after perusal of his book is that further work is still necessary in several directions before finality can be reached.

The more one works with B.C.G., and the more one reads of the work of others, the more difficult does it appear either to prove or disprove the claims made for this vaccine by Calmette and his supporters. As to the power to evoke increased resistance in animals which B.C.G. possesses, in common with other strains of tubercle bacilli, when correctly used in appropriate doses, this is established beyond doubt—as was, indeed, to be expected. But whether the oral administration of "safe" doses of B.C.G. to infants is of any use as a prophylactic remains to be proved. Greenwood has shown that the French statistics so far produced are unsatisfactory, but this is no proof that B.C.G. is inefficient. It is clear that further and better tests are desirable. As Ascoli suggests, however, the employment of B.C.G. should be confined to infants in close contact with infected parents or other infected persons. Its use for infants *not* known to be exposed to the immediate risk of infection cannot be regarded as advisable at the present time, and is calculated to lead to further confusion in attempts to evaluate the vaccine by statistical methods.

We have received also a copy of the authorized French translation of Professor Ascoli's book. This, like the original work, is published in Milan.[2]

TONSILS AND ADENOIDS.

DR. IRWIN MOORE has embodied in one volume, under the title *The Tonsils and Adenoids and their Diseases*,[3] a number of papers which he has contributed to various medical journals during recent years, dealing with the important subject of enlarged or diseased tonsils and adenoids—their menace to health, the operative technique for their removal, and the control of haemorrhage, during and after removal.

The most important chapter, and perhaps the one that will be read with the greatest interest at the present time, is that dealing with haemorrhage following the surgical removal of the tonsils and its treatment. Ten years ago the author drew the serious attention of the profession to the frequency with which haemorrhage followed the operation, and expressed surprise at the casual way in which operations upon the tonsils were being performed, regardless of heavy loss of blood, and, in the majority of cases,

[2] *La Vaccination Antituberculeuse avec les Bacilles Vivants chez les Animaux et chez l'Homme.* Par Alberto Ascoli. Édition française [illegible] (par suppression des protocoles d'expériences, des clichés et des [illegible] détaillés) par le Dr. M. Carrel. Milano: Istituto Editoriale Cisalpino. 1928.

[3] *The Tonsils and Adenoids and their Diseases.* By Irwin Moore, M.D., C.M.Ed. London: W. Heinemann (Medical Books) Ltd. 1928. (9 × 6, pp. ix + 395; 107 figures. 21s. net.)

without any steps being taken to control the bleeding at the time of the operation, with the idea that it would sooner or later cease of its own accord.

When the British Medical Association met at Newcastle-upon-Tyne in July, 1921, the meeting of the Section of Oto-Rhino-Laryngology, under the presidency of the late Dr. William Hill, was largely devoted to papers (*British Medical Journal*, 1921, vol. ii, pp. 431–446), and discussions dealing with "Problems presented by haemorrhage following operations on the tonsils." Dr. Irwin Moore, acknowledging the service those papers have been to him, observes that they give a complete and up-to-date résumé of the subject, and represent an accumulation of information and detail not dealt with in the usual textbooks, and obtained only by much labour in extensive search into the literature. The chapter on haemorrhage occupies one-fifth of the volume, an amount of space not out of proportion to the importance of the subject. A perusal of the chapter at once disposes of the optimistic view held by some that the operations as performed to-day are trivial ones. It having been shown that the operation is not entirely free from alarming and sometimes dangerous results, the question naturally arises for careful consideration what are the "indications for, and result of treatment of, chronic tonsillitis." In 1924 (*British Medical Journal*, 1924, vol. ii, pp. 804–813), at the meeting of the British Medical Association at Bradford, the Section of Laryngology and Otology chose that subject for discussion. Dr. Irwin Moore deals with the question in a separate chapter entitled "The tonsils as a source of focal infection in systemic diseases and the results obtained by tonsillectomy," and acknowledges considerable service derived from the opening paper at that meeting in revising this chapter. The methods for the surgical removal of the tonsils are fully described and illustrated. The treatment of enlarged or diseased tonsils in cases in which surgical procedures are contraindicated is a chapter in itself.

A remarkable feature of the book, and one that must enhance its value as a work of reference, is the mass of references compiled in alphabetical order at the end of each chapter. The author has achieved his purpose to produce in a monograph the accumulation and concentration of the present-day knowledge of the tonsils and the part they play in health and disease.

SURGICAL DIAGNOSIS IN TABULAR OUTLINE.

THE translation by Dr. BORTZ of Philadelphia of the fourth German edition of the work of Dr. CEMACH of Vienna is the first appearance of the book[1] in an English dress, as Dr. JOHN B. DEAVER tells us in an introductory note. In the translator's foreword we are told that Dr. Bortz has had the help of other specialists in its production, and that he has added to the information provided in the last German edition. We think that Dr. Bortz is justified in his statement that "the author has furnished an exceptional amount of useful information in an easily accessible form." The general plan of the book is that a plate representing a number of diseased conditions is followed by a large folding table, on which, in a number of columns and compartments, are set forth the nomenclature and varieties of the conditions dealt with, their history and etiology, symptoms, situation, the results of examinations, and the diagnosis. There are 129 such plates and over one hundred tables, but as most tables are equivalent to two pages, the typed matter is equivalent to some two hundred pages.

Such a method of providing information has its advantages if its use is made only a *preliminary* to a further study of the subject in monographs or textbooks. A reference to these tables may serve to remind the practitioner who consults them of the existence of some condition that might otherwise have escaped him. For information as to treatment he must, of course, look elsewhere.

Despite the size of this book and its wealth of illustrations, there are some lacunae in its scope and some conditions that are barely mentioned, such as Dupuytren's contraction of the palmar fascia. For example, we have failed to find any references to certain not uncommon congenital defects of the skeleton, such as so-called intra-uterine amputation, defect of tibia or radius, etc., although congenital club-foot and congenital dislocation of the hip are represented. Gastric ulcer, Legge's disease of the hip, and cystic bone disease are also unrepresented. We say advisedly "we have failed to find," because the index is singularly meagre for such a work, and although we have spent much time in turning over the pages, we may have missed some small references, such as that devoted to Dupuytren's contraction. The section on injuries of the spine is very superficial and gives little help in the diagnosis, say, of compression fracture of a lumbar vertebra, which is not uncommon and is very important industrially. The illustrations vary in merit. Some of the *x*-ray pictures are obscure, but others are good. We think that it is a mistake to represent diseases such as tumours by cases at these very advanced stages. It is probably for help in the early stages that the practitioner will turn to this book, and he will get little assistance from contemplating pictures of fungating tumours.

The outside cover of this volume bears the words "For desk use." Certainly no one would think of trying to carry it in a pocket, for it weighs four pounds, and its size has already been indicated. It would be unkind to suppose that the practitioner is meant to look up the diagnosis while the patient waits. To the letterpress is appended a copious bibliography of works in German and in English in separate paragraphs.

DISORDERS OF THE SYMPATHETIC-AUTONOMIC SYSTEM.

THE first edition of Dr. Guillaume's *Vagotonies, Sympathicotonies, Neurotonies*[2] was immediately successful, and the second edition is likely to be equally so. It has undergone thorough revision, but has preserved all the characteristic features of its predecessor. Much new matter has been included, and, in particular, there are additional chapters, one of which describes the various changes in the blood found in cases of disorder of the vegetative nervous system, and another the psychical concomitants of vegetative nervous system disturbance. With regard to the latter, Dr. Guillaume points out that signs of such disturbance are rarely found in the major psychoses, though in the psychoneurotic states they are relatively frequent. This work is a study of the dysfunction of the sympathetic-autonomic system, chiefly from a clinical point of view; but etiological and therapeutic considerations are not neglected. The classification adopted by the author is essentially clinical. The three conditions which give the book its title are fully described. Under the heading of neurotonia, Dr. Guillaume discusses the peculiar instability of the tonus of the organs subject to the control of the vegetative nervous system, and, in particular, their excessive and violent response to all manner of stimuli. He describes also, under the heading "neurotonie alternante," the condition of successive phases of vagotonia and sympathicotonia. The passages devoted to the differential diagnosis of the many morbid states of the vegetative system are especially to be commended. Numerous hints are given as to the technique of eliciting the various reflexes (oculo-cardiac, etc.). There are several helpful diagrams, many references throughout the text to the findings of other workers in this field, and a voluminous bibliography.

A NEW HYPOTHESIS OF LIFE.

MRS. AUGUSTA GASKELL, who is introduced by KARL T. COMPTON, professor of physics at Princeton, and RAYMOND PEARL, professor of biology at the Johns Hopkins University, has attacked the great problem *What is Life?*[3] Her first sponsor says that her discussion of modern atomic physics is accurate, well balanced, and worth reading for its own

[1] *Surgical Diagnosis in Tabular Outline.* By Dr. A. J. Cemach, Vienna. Authorized translation with additions and notes by Edward L. Bortz, M.D., with an introduction by John B. Deaver, M.D. Philadelphia: F. A. Davis Company. 1928. (7 × 11; 128 plates; 109 tables. 12 dollars net.)

[2] *Vagotonies, Sympathicotonies, Neurotonies.* Par A. C. Guillaume. Deuxième édition, entièrement refondue. Paris: Masson et Cie. 1928. (8½×8½, pp. xxiv+532; 18 figures. 40 fr. sans majoration.)

sake," and that her fundamental assumption must be admitted as possible. Professor Pearl somewhat guardedly gives his blessing by saying that her hypothesis has the advantage over others in that it is capable of experimental proof (though this is admittedly not easy to attain); that her book is free from "hedging" and "alibis carefully made ready in advance"; and that her discussion of various biological problems, particularly of evolution, have a refreshing novelty and shrewdness. As the problem is one to daunt the bravest of men and even of women, it is not surprising that the professors of physics and biology, who are quoted in the text, have been called in as accessories. Mrs. Gaskell writes modestly, in good English, and obviously with the advantage of wide access to the literature of the sciences concerned. Her hypothesis, based on atomic physics, is that the protons and electrons, besides forming by their various known combinations the ninety-two kinds of atoms, are able to unite in combinations of a type which are the active or essential ingredients of living matter. These so-called "Z"-elements are immaterial, intra-atomic, and, with the material ("Y") system of protons and electrons, make up the dual system of living matter. Life is regarded as a quantity—not of matter or of undefined or indefinable energy, but of the same constituents which make up matter, combined in a different manner. The soul is identified with life, and death is ascribed to separation between the two constituents of the dual system of living matter. Mrs. Gaskell discusses the origin of species with many quotations from Jacques Loeb, Bateson, and others, and comes to the conclusion that the current doctrine of man's descent is erroneous and that heredity is due to the constitution, the organization, and the pattern of the "Z"-system of the germ cell, and not to the chemical constitution of the matter ("Y"-system) of the germ cell. The final proof of this revolutionary hypothesis of life consists in testing for and measuring at the time of death the "Z"-system—the quantity life—which, according to the hypothesis, then becomes separated from the body—the atomic or the "Y"-system. Raymond Pearl prophesies that this book, unless a miracle happens whereby normal human behaviour is temporarily changed, "will doubtless receive its due measure of the violent opposition which every new idea regularly receives." It contains a very useful glossary of technical terms.

NOTES ON BOOKS.

WE have received a fourth edition of Dr. R. D. LAWRENCE'S *The Diabetic Life*,[7] of which the third edition was reviewed in these columns just over a year ago. Most of the changes are in points of detail, but more attention has been given to the treatment of coma and of intercurrent illnesses, as these are regarded by the author as being by far the most difficult and dangerous problems which the treatment of diabetes presents. Considerable modification has, however, been made in the tables of food values for carbohydrates, in so far as fruits and vegetables are concerned, in the light of research carried on in recent years. Dr. Lawrence's work is now available also in a French translation[8] which has been made from the second English edition.

The manual by Mrs. ANNE M. ROBERTSON entitled *Health and Exercise for Girls*[9] is a book that might usefully be added to a children's library, as it contains nothing which can in any way encourage the study of ill health. The author makes her introductory remarks in the form of an open letter to girls, in which she gives in very simple language the reasons for taking thought in order to be healthy. She says that "those people who, like the Greeks, have striven to improve their personal and individual lives have attained to the greatest wisdom and happiness that we know of." In the first part of the book the purpose and care of the different parts of the body are indicated in allegorical form, by comparing the body to a house. The final chapter on "The beauty of health" will probably appeal to adolescent girls. Part II contains a group of practical exercises for growing girls, arranged by Mr. F. Hornibrook, and a few words are devoted to the discussi of the value of systematic exercise. Eight simple exercise founded on movements of primitive tribes, are then describe with good illustrations.

Dr. CARL FUNCK, in a pamphlet on nutritive allergy, mentions that as early as the year 1914 he recognized t altered condition of the organism which follows the entry alien proteins into the blood stream through the digestive tra —the condition to which von Pirquet has given the nar "allergy." Dr. Funck discusses the whole problem of hype sensibilization of the tissues by alien proteins and their inte mediate products of decomposition, with special reference the part played by intestinal absorption and assimilation ar the influence of this nutritive allergy in the pathogenesis internal disease. His observations go to prove that ev where the sensibilization can be definitely referred to an age acting through the skin or respiratory tract, it often happe that removal of the cause is insufficient in itself to effect a cur unless treatment is directed at the same time to the digestiv tract.

Medical practitioners and medicine have often figured i novels, but few works of fiction give so graphic and symp thetic an exposition of these subjects as *My Brother Jonathan*, by FRANCIS BRETT YOUNG. The author, himself a doctor, h a delicate appreciation of words, a gift for vivid characte drawing, and a true dramatic instinct. His story is of th family of Dakers, living and working in the Midlands. Th two brothers, Jonathan and Harold, have a curious upbringin by their father. Jonathan, plain and dull, is neglected, almo scorned; Harold is full of charm and grace, and on him showered all the family affection. Jonathan develops into man of strong character, full of human sympathy and th instinct of self-sacrifice. Hal goes to Harrow and Cambridge wins his blue for cricket, all at the expense of his elde brother. Jonathan goes to the provincial medical school, where he gradually escapes from the repressions of the hobbledehoy, makes his mark in his hospital, and bids fair to become surgeon of note. But he sacrifices this prospect to save hi brother. He joins a worn-out lion-hearted general practitione in a sordid town in the Black Country, and there follows the tale of his struggle against local medical and social ostracism. He wins his place in the affections of the people by love of work and love of human nature. The effect of the incomin of the Insurance Act is told (but it is odd that the author makes his hero resign his membership of the British Medical Association in defence of one of the cardinal points of the Association's policy—"free choice of doctor"), and the effect of the great war. The book is a romance, and there are the love stories of four people, two men and two women. The latter part of the book is almost too tragic. But it is a great story, finely conceived and finely written.

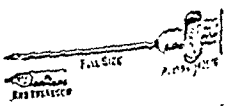
PREPARATIONS AND APPLIANCES.

NEEDLE FOR INJECTION OF VARICOSE VEINS.

DR. T. H. TREVES BARBER (London, S.W.) writes: The two main essentials for the successful treatment of varicose veins by the injection method are that the solution shall be brought into as close contact with the endothelium as possible and at its highest concentration.

This needle has been designed for the purpose of meeting these desiderata by the direction given to the spray; the tip being laterally placed, enables the solution to be injected at an obtuse angle to the wall of the vein. There is less danger of the solution being injected into the wall of the vein instead of into the lumen, owing to the very short bevel and the distance from it to the eye of the needle. With an ordinary hypodermic needle such an event is liable to happen, especially with a long point and bevel. Owing to the position of the eye there is less likelihood of it being blocked as it penetrates the tissues to enter the vein.



Finally, any direction may be given to the spray by a rotation of the syringe. The lettering "REGD." stamped on the mount should be noted, as it indicates the direction of the eye in relation to the walls of the vein; it is thus possible to make a complete ring around the wall with the solution. This method will be found useful in treating dilated veins. The needles are made by Messrs. Allen and Hanburys Ltd., 48, Wigmore Street, W.1.

ADENOIDS AND ENLARGED TONSILS.

BOARD OF EDUCATION INQUIRY.

HE method of statistical analysis, though appropriate to ie investigation of conditions so widespread as adenoids id enlarged tonsils, presents difficulties which may be vercome only by the exercise of considerable caution. The ccumulation of statistical data must be entrusted to a umber of workers who may differ as to the interpretation f the phrase "enlarged tonsils and adenoids," and may ave varying standards regarding associated conditions—r example, nutrition—included within the scope of nquiry. Complete mathematical accuracy may be unttainable, but the interim report,[1] just published, of an nvestigation conducted by a medical committee of the oard of Education during the period 1924 to 1928 suggests iat at least it is possible to achieve a general indication the truth.

Scope of the Investigation.

The terms of reference of the committee were to inquire to the incidence of, and the physical and environmental nditions associated with, enlarged tonsils and adenoids, id into the method and results of treatment. The first ep, therefore, was to seek information as to the significe of hereditary and familial influences; the influence social and domestic environment, of diet in the early ars of life, and of childhood infections and ailments; the sociation of the conditions with malnutrition, constitunal disease, oral sepsis, and special defects and mptoms; and, finally, the subsequent history as regards neral health and special defects of children who had dergone treatment, as compared with others who had en left untreated. The total number of children subtted to examination was 640, of whom, after a certain ount of preliminary redistribution, 502 were cases—that children found to be suffering from one or both of the nditions in question—and 138 were controls—that is, ldren whose nasopharynx was apparently normal. The rage age at first examination of the cases was 6 years months; of the controls 6 years 9.5 months. In the up of "cases," 382 children, of whom 40 at some time other had already been submitted to operation, were fering from both enlarged tonsils and adenoids; 47 had noids only, and 75 only enlarged or septic tonsils.

Influence of Heredity.

n comparing the families of the control group with se of the group of "cases," enlarged tonsils and noids were found to occur more than twice as often in latter as in the former. Thus a family history of this ect was recorded in respect of 57 per cent. of the up of "cases," and only of 24.6 per cent. of the group ontrols.

Social Conditions and Diet.

stimation of the significance of data concerning hous- dietary, and modes of living is complicated by the that the mere prevalence of a pathological condition were crowded or insanitary dwellings is no proof that environment *per se* has etiological significance; the estic circumstances may do no more than indicate rty or neglect, and these, again, may be associated defects of diet and unhygienic practices. The comee found that though there was no substantial differas regards the extent of accommodation between the groups, the condition of the housing accommodation, as cated by the presence or absence of damp and sanitary cts, was better in the group of controls. The inquiry o diet suggests somewhat less favourable nutritional litions of ante-natal and early post-natal life, and later rer supply of vitamins in the food of children in the p of "cases" than in the controls.

Health During Infancy and Childhood.

ie most striking contrast is afforded by the data coning the health of the two groups during their first of life: 30.7 per cent. of "cases" were said to have been generally in poor health during this period, as compared with only 4.3 per cent. of controls. Nasal or bronchial catarrh and allied conditions, general feebleness and malnutrition, and digestive troubles were met with most frequently. In regard to infectious diseases—for example, whooping-cough, measles, mumps—these are equally prevalent in both groups during the first year of life; but during school life the incidence of infectious diseases is uniformly higher among children with enlarged tonsils and adenoids than among normal children. So frequently, moreover, do parents report the onset of the nasopharyngeal condition after an attack of infectious disease that it may reasonably be assumed that in a considerable proportion of cases there is a direct causal relation. In some cases the febrile attack is probably an exciting cause of hypertrophy of lymphoid tissue in an already predisposed child; in others the infection may be the consequence rather than the cause of the nasopharyngeal condition; and, finally, the possibility must be considered of some fundamental constitutional weakness, which is the common cause of both conditions. Inquiry among parents as to the medical history of the children prior to examination elicited information which points to the presence of a tendency to catarrhal conditions of the nose and throat in the group of "cases" nearly double that in the group of controls; to ear disorders five times, and to diarrhœa eight times that in the controls. Thus 81.5 per cent. of "cases" and 44.2 per cent. of controls were liable to colds; 18.7 per cent. of "cases" and 3.1 per cent. of controls had suffered from otorrhœa, and 12.2 per cent. of "cases" and 1.6 per cent. of controls from diarrhœa. A condition of oral sepsis was found in 17.5 per cent. of the "cases" and in 8 per cent. of the controls. In simple enlargement of tonsils without adenoids oral sepsis was present in 13.1 per cent. and in cases of septic tonsils with or without adenoids in 20.6 per cent. Oral sepsis is thus more than twice as frequent in the group of "cases" as in normal children. But whether the definite association between the two conditions indicated by this fact is one of cause or effect can only be determined by further investigation.

The Age of Onset.

The age at which symptoms first became manifest in the younger group of children was 5.3 years, in the older group 7.3 years. If, as seems reasonable to assume, the condition is usually established before symptoms are noted by the parents, it would appear that adenoids develop in the majority of cases before five years of age, and that it is unusual for them to arise after the age of 7 or 8. Enlargement of tonsils may occur at any time during school life.

General Condition of Cases and Controls.

The relationship of subnormal health to enlarged tonsils and adenoids can only be determined by the continued observation of a large number of children before the onset of symptoms. In only forty-six of those studied in the present inquiry—too small a number to justify any conclusions—did the condition develop in the course of following up; in the remainder the differences in general condition between cases and controls might represent either causes or results. In general appearance, 12 per cent. of "cases" seemed unhealthy, as against only 0.8 per cent. of controls. Under 6 years of age the proportion of unhealthy children was as high as 16.2 per cent. In the group of "cases" the nutrition of 45.2 per cent. was good, of 50.8 per cent. moderate, and of 4 per cent. it was bad. In the controls it was good in 58.5 per cent., moderate in 40.8 per cent., and bad in 0.7 per cent. No significant difference was found in the heights of the two groups, which appeared to approximate closely at all ages, but in regard to both weight and chest measurement, from the age of 6 years the controls were consistently, though not greatly, better than the "cases." It is noteworthy that up to 6 years of age the inferiority of the group of "cases," though obvious on inspection, was not demonstrable by measurement. One must assume that the indications of defective nutrition obtained by observation are as reliable as those obtained by simple measurements, and there seems

[1] Board of Education, Interim Report of the Medical Committee on Adenoids and Enlarged Tonsils. 1929. H.M. Stationery Office, or through any bookseller. Price 6d. net.

no reason to doubt that from birth to the end of school life the cases under consideration show a lower standard of physique and general nutrition than the normal child.

Respiratory and Circulatory Systems.

Children with adenoids are far more susceptible than others to catarrhal affections of the respiratory tract. The lungs were normal in 75.9 per cent. of the "cases," and in 93.2 per cent. of the controls. Bronchial catarrh was present in 18.3 per cent. and defective air entry or poor expansion in 5.7 per cent. of the "cases," as compared with 3.1 per cent. and 3.8 per cent. respectively in the controls. Defects of the heart and circulatory systems were equally prevalent in the two groups, there being 3.2 per cent. among the "cases" and 3.1 per cent. among the controls. So far as cardiac defects are an indication of rheumatism there is very little here to suggest the close association so often alleged between this disease and enlarged tonsils and adenoids. It is significant, however, that though a history of rheumatism was recorded in only 6 out of 627 children examined, all these 6 were in the group of "cases."

Other Pathological Conditions.

The proportion of rachitic children among the "cases" was higher than among the controls, being 7.8 per cent. in the former group and only 3.8 per cent. in the latter. These figures suggest the possibility that deficiency of vitamin D, known to be the essential cause of rickets, may also be an important factor in the production of naso-pharyngeal abnormalities. It seems reasonable to suppose that a large number of children may suffer from vitamin deficiency too slight to cause clinical rickets, but enough to bring about defects whose etiology has hitherto been little understood. Signs of tuberculosis were observed in 2.1 per cent., and syphilis in 0.8 per cent. of "cases"; no signs of either disease were recorded among the controls.

Educational Standard.

Educational retardation is a fairly common result of adenoids, especially in the higher age groups. Of the cases under review 20.5 per cent. were retarded, as compared with 6.7 per cent. in the group of controls. Of the children under 6 years of age the percentage retarded was 9.7, between 6 and 10 years it was 24.7, and over 10 years 40.6. The cause of backwardness in a certain number of cases is defective hearing; in others there is a certain mental lethargy, which may be due to interference with the circulation in the frontal lobes. Whether intelligence as measured by the usual tests is actually lower than the normal does not seem to have been determined, and the committee suggests that this is a point worth investigating, particularly by a series of tests to ascertain whether any improvement in the intelligence quotient follows the removal of the adenoids.

Association of Special Symptoms.

In working out the correlation of special symptoms with the nasopharyngeal condition it was found convenient to classify the cases in three groups: A, cases with involvement of tonsils only; B, with only adenoids; and C, with adenoids and involvement of tonsils. Of 413 cases examined 53 fell into Group A, 40 into B, and 315 into C. Mouth breathing and snoring, pointing to nasal obstruction, were commonest in C (75.0 and 74.3 per cent. respectively), somewhat less in B (52.5 and 67.5), and least in A (31.0 and 34.5). Examination of the nasal passages showed significant differences between the three groups in regard to actual defects in the passages, and a much greater frequency of nasal catarrh in those children with adenoids. In Group C, for example, 15.6 per cent. had hypertrophied turbinals, in Group B 7.5 per cent., and in Group A only 5.2 per cent. Among the controls similarly examined there were only two with hypertrophied turbinals.

Sleep disturbances, which may be associated with nasal obstruction, with irritation of the bronchial passages, or with interference with the cerebral circulation, are more common in children with adenoids than in normal children; 54.2 per cent. of the "cases" were recorded as suffering from disturbed sleep, as compared with 15.7 per cent. of the controls. Correlating disturbed sleep with the three above-named groups, it was found that the condition appeared in 59.0 per cent. of Group C, in 55.0 per cent. of Group B, and in 27.6 per cent. of Group A. Defective hearing was recorded in respect of 27.4 per cent. of "cases," and signs of chronic otitis in 27.8 per cent. Defective hearing was commonest in Group B, least common in Group A. Enlargement of tonsils, though liable to cause deafness in chronic cases, appears, therefore, to be a far less potent cause of this defect than adenoids. Varying degrees of enlargement of the cervical glands were recorded in 69.0 per cent. of "cases." This condition occurred most frequently in Group C, and least in Group A. Speech defects, for the most part attributable to mouth breathing and defective hearing, were most prevalent in Group C (21.6 per cent.), less in Group B (12.5 per cent.), and least of all in Group A (6.9 per cent.). A tendency to febrile attacks was reported in respect of 26.4 per cent. of the cases, as compared with only 1.5 per cent. of the controls. Whatever the causes of these attacks, which probably include a variety of minor infective processes, they are obviously associated with tonsils and adenoids, and particularly with the two conditions combined. Enuresis was somewhat more common in all groups of "cases" than among the controls.

After-History of Enlarged Tonsils and Adenoids.

The committee has records of 63 children in the group of "cases" who, for varying periods (the average being 1 year and 4 months), were untreated; 43 of these had enlarged tonsils and adenoids, 10 had adenoids only, and 10 only enlarged tonsils. During the period in question none of the 10 with only tonsils developed adenoids; in 3 the tonsillar enlargement increased; in 1 it diminished, and in 2 it disappeared. Of the 53 cases with adenoids these growths increased in 6, improved in 6, and in 5 underwent spontaneous cure. Tonsillar enlargement, present originally in 37, developed in 6 others during the follow-up, increased in 8, was unchanged in 18, decreased in 2, and disappeared in 9. It is noteworthy that none of the children whose adenoids or enlarged tonsils spontaneously cleared up was under 6 years of age. Spontaneous improvement appears to have been generally accompanied by amelioration of associated symptoms.

Results of Operations.

During the period of observation 131 children had their adenoids removed, the time between operation and the final re-examination varying from a few weeks to two years. The various associated symptoms were in many instances apparently cured; in some they were improved or unchanged; in a few they became worse. Figures obtained from an investigation of a small group of children re-examined one to six years after operation (the average interval being four years) suggest the possibility that the early improvement after operation is not always maintained. This is particularly noticeable with respect to nutrition, in which an improvement was observed in a majority of cases, but in only 20 per cent. of cases re-examined after some years. Possibly the circumstances of many a child after operation are for a time more favourable than usual, and the operation may be credited with an improvement due in reality to other causes. Otorrhœa seems to have been but little affected by operations for tonsils and adenoids, but the majority of cases of nasal catarrh were cured as the result of operation. Bronchial catarrh does not seem to benefit to the same extent, only 10 cases being cured out of 27. A tendency to sore throat was remedied in 21 out of 26 cases.

Further Investigations.

The committee has decided to undertake the systematic examination of a series of unselected children from birth in order to ascertain the facts in their early history and conditions which are associated with the onset of enlarged tonsils and adenoids. Their examinations will include a detailed inquiry into maternal history during pregnancy, the dietary of the child during early life, as well as a careful record of the dental condition. Further inquiry will relate to the frequency of association of certain abnormalities suggestive of vitamin deficiency with enlarged tonsils and adenoids.

British Medical Journal.

SATURDAY, FEBRUARY 16TH, 1929.

THE SIGNIFICANCE OF IODINE.

To those of our profession who are engaged in practice, in teaching, or in research, or who, perhaps, try to combine at least two of these in their daily tasks, the scientific review is becoming more and more a necessity. It is impossible to be reasonably well informed upon any subject without keeping in touch with current literature; yet, over a narrow range of subjects, it is equally impossible to read, much less to criticize or appreciate, the contents of more than a very few of the specialized journals. We must rely, therefore, upon publications in which scientific work is condensed, analysed, and presented in a critical manner; nor ought we to be slow in acknowledging our indebtedness to those who undertake the laborious task of preparing reports, and to the bodies under whose auspices such reports are published.

The Medical Research Council's Special Report, No. 123, on "Iodine in nutrition," prepared by Drs. J. B. Orr and L. Leitch, certainly does not fall short of the standard set by previous communications published by the same body. A study of the section headings alone gives some idea of the extent of the matter treated and of the thoroughness with which the authors have done their work. The discovery of iodine depended on the chance observation of a French nitrate manufacturer in the early part of the last century. Investigation has since shown it to be ubiquitous; it is present in earth, air, and sea. It stands in a very special relation to biological processes, and neither the animal nor the vegetable world can remain indifferent to its presence or absence. Living cells possess a curious property which enables them to store up iodine obtained from their surroundings, and it is clearly no accident that our chief sources of iodine supply are deposits gathered by living agencies—seaweeds and guano beds. It has been shown that an optimal concentration of iodine increases the yield of crops and the growth of domestic animals. Manures and cattle foods may both be enriched with iodine. Clearly, the study of the iodine content of soils and its availability for living matter is an important subject for the agriculturist. Some soils, it appears, give up their iodine more readily than others, while the common manures vary widely in iodine content.

It is natural for us to think of iodine in connexion with the thyroid gland; indeed, while we reckon the iodine content of soils and water in micrograms (millionths of a gram) per kilogram, in the thyroid it is present in amounts up to 0.04 gram per 100 grams of fresh tissue. The animal body, apparently, has found it necessary to set aside certain tissues in which the power of collecting iodine, common to all cells, is intensified to a very special degree. It is, perhaps, an example of chemical specialization, comparable with the functional specialization familiar to us in muscle, nerve, and the like. Medical interest has, of course, long been focused on goitre. The ancients treated the disease with burnt sponge—an iodine-rich material—and forty-five years before Baumann discovered iodine in the thyroid gland Chatin was endeavouring to treat goitre by the administration of iodine. The early French experiments proved a disastrous failure, chiefly on account of the dangerously high doses administered; it was only later, as the effectiveness of minute doses of iodine came to be appreciated, that such methods proved their real value. In the biochemical study of the thyroid gland the chief landmarks of recent years have been Kenda's isolation and Harington's synthesis of thyroxin. It was recognized before that the iodine of the thyroid was in organic combination, but the isolation of an organic substance, the discovery of its constitution, and the demonstration that its effects are identical with those of the whole thyroid gland, have made possible the quantitative observations so desirable in scientific work.

It is of the greatest interest that, although iodine is physiologically very active, its effects are not the same as those of thyroxin; evidently the body finds the manufactured article more suited to its needs than the raw material. Certain types of simple goitre can be successfully treated by potassium iodide; and, so far as we know, we are here dealing with a straightforward replacement. On the other hand, Graves's disease, the symptoms of which strongly suggest hyperthyroidism, can also be successfully treated by inorganic iodine. Now Hildebrandt found that while injection of thyroxin caused a rise in the basal metabolic rate of rats, injection of inorganic iodine caused a fall. If an injection of thyroxin was later followed by one of inorganic iodine the same phenomena occurred, but the threshold for the inorganic iodine effect was much lowered. Thus, while in the normal rat 0.5 mg. of iodine caused an observable fall in the basal metabolic rate, some time after thyroxin injection the same effect was produced by 0.01 mg. The explanation of this phenomenon has yet to be found, but the analogy between it and the behaviour of iodine in hyperthyroidism is obvious. In a recent paper Kendall[1] has brought forward evidence to show that thyroxin is neither the only nor the most physiologically active inorganic iodine compound in the thyroid. Indeed, from some samples of dried thyroid possessing marked physiological activity he was unable to isolate any thyroxin at all. Suggestive as such observations are, they must, of course, survive the test of further investigation before they can be finally accepted.

Perhaps the strongest impression left on the mind by the report of Orr and Leitch is that iodine possesses some fundamental significance for life which hitherto has eluded us completely. Hardly a cell remains indifferent to it; iodine deficiency affects almost every function and every tissue in the body. Preoccupation with purely pathological matters has perhaps blinded us to the wider significance of our observations; yet it seems that we shall have to extend our horizon considerably before we can grasp the true significance of this element for the processes of life.

TRAFFIC IN DANGEROUS DRUGS.

THE medical profession has a special interest in the suppression of drug addiction, and therefore the efforts of the League of Nations to check the illicit traffic in drugs deserve the sympathetic attention of our readers. The Council of the League receives reports from an advisory committee on traffic in opium and other dangerous drugs, which meets once or twice a year. The problems that confront the committee are of extraordinary complexity, but some idea of a few outstanding facts can be gathered from the report of the eleventh session that was published last summer.[2]

[1] *Journ. Biol. Chem.*, December, 1928, 80, p. 837.
[2] Minutes of the Eleventh Session of the League of Nations Advisory Committee on Traffic in Opium and Other Dangerous Drugs. C.328, M.88, 1928, xi, p. 364.

There are really two problems involved: first, that of opium smoking and opium eating in the Far East, and secondly, that of the abuse of the alkaloids morphine, heroin, cocaine, etc. This latter is a problem that is in no way limited to the Far East, for the abuse of these drugs is a danger that threatens every country in the world. The two problems are linked by the fact that limitation of the production of alkaloids is made much more difficult by any excessive production of the raw materials. While abuse of the alkaloids constitutes practically the entire problem of drug-habit formation among Western nations, these alkaloids are rapidly finding a market also in the East. The evils produced by the older vices of opium smoking and eating are bad enough, but it would probably be agreed that the effects of alkaloid addiction are much worse. Indeed, the aggravation of the evil produced by the change from opium to morphine has been compared to the effect of substituting gin for beer in England in the first half of the eighteenth century. In the report quoted M. Chao (China) went so far as to say: "The effect of this new danger is at present so appalling that many Chinese social leaders have expressed their readiness to reintroduce opium smoking if this would put an end to the use of morphine"; and later he quoted the popular opinion that opium smoking may be regarded as, on the whole, a harmless habit, and easily curable in comparison with the new drug addiction.

Now the smuggling of alkaloids is far easier than the smuggling of opium. The extent of the trade is indicated by the statement that in 1926 3.77 tons of smuggled alkaloids were seized or traced in China. The usual assumption for Western countries is that seizures represent 10 per cent. of the total traffic, but this is probably far too high a figure for a country so disturbed as China. The total legitimate need in the world for these drugs has been estimated to be approximately as follows: morphine 20 tons, heroin 2 tons, cocaine 12 tons. If M. Chao's figures are correct they imply that the amounts of morphine and heroin smuggled into China annually are greater than the total annual legitimate world requirements for these drugs. It is obvious that European civilization has a grave responsibility in this matter, since the greater part of these alkaloids is manufactured in Europe. Europe has a definite duty in regard to the illicit traffic in dangerous drugs, because Article 9 of The Hague Opium Convention of 1912 requires the contracting powers to limit their manufacture to medical and legitimate needs, and by Article 13 they agree to control their exports of these substances.

The illicit trade in morphine and cocaine is, of course, not confined to China. Sir Malcolm Delevingne described the situation in China as being far the most serious, but mentioned that the illicit traffic was still very serious in the United States of America and in Canada, and also in the Eastern Mediterranean. Egypt was stated to be inundated by contraband drugs. The view of the United States Government is that on account of the portability of the drugs and the enormous profits accruing from their illicit traffic it is almost impossible to control this evil by customs, and that the only hope of improvement lies in limiting the world manufacture of drugs of addiction to quantities commensurate with legitimate medicinal needs. Unfortunately the quantity manufactured appears to be actually rising, since it is estimated that the world production of morphine was 60 tons in 1926, as compared with 30 tons in 1921. In this connexion a new difficulty arises in that it is stated that nearly half the morphine manufactured is turned into codeine. Now it is generally admitted that codeine is not so apt to cause addiction as morphine or heroin, but the fact that so large a proportion of morphine disappears from control in this manner greatly increases the difficulty of keeping track of the morphine produced. Moreover, chemists have recently produced two new compounds—eucodal (derived from thebaine) and dicodide (derived from codeine)—and the expert committee of the League of Nations holds that both are habit-forming drugs. Reports from America indicate that they are already well known to the dope vendors in that country. It is believed that there are only about forty factories engaged in the production of habit-producing alkaloids, and figures for the manufacture, export, and import of these drugs for several nations are given in an appendix to the report; but, unfortunately, they fail to explain the origin of the immense quantities well known to be passing through clandestine channels. We referred in our issue of February 2nd (p. 213) to the disclosure, at a meeting of the League advisory committee, of the existence of an enormous traffic in morphine, heroin, and cocaine of Swiss manufacture carried on by a Dutch firm, now suppressed, trading largely through Viennese agencies, with the Far East. Since then Sir Malcolm Delevingne has given further details about the widespread ramifications of this illicit drug traffic, in the course of an address to the League of Nations Parliamentary Committee, at the House of Commons on February 11th.

It appears to be generally agreed that addiction to morphine, heroin, and cocaine has increased very greatly during the past decade, and the members of the advisory committee did not consider last year that the back of the illicit traffic had yet been broken. Apart from the damage done to individuals, this traffic obviously constitutes a serious source of international ill will, since countries that have taken pains to regulate their drug manufacture naturally resent being flooded with poisons from countries that are less careful or less scrupulous.

MINOR INJURIES OF THE VERTEBRAE.

At the joint meeting of the Surgical and War Sections of the Royal Society of Medicine, reported in this issue at page 298, Group-Captain H. V. Wells raised a question to which it is not easy to find an answer. He asked for information and guidance as to the diagnosis and early treatment of what might be called masked spinal injury—that is, a condition in which symptoms appear and radiological examination shows alterations in the shape and density of one or more vertebrae long after recovery from the original shock has apparently occurred. Sir Percy Sargent agreed as to the occurrence of these late symptoms, and asserted categorically that a spine which appeared normal radiographically immediately after the accident might show atrophy and collapse of one or more vertebral bodies many months afterwards. He attributed the symptoms to injury, at the time of the original accident, of muscles supporting the spinal column, and to a subsequent yielding of the vertebral body or bodies deprived of their normal muscular support. Most of those who took part in the discussion accepted the clinical picture drawn by Captain Wells, but were generally unable to offer a satisfactory explanation of its pathology. Dr. Bertram Shine, however, was sceptical about the alleged normal condition of the bone immediately after the injury. He thought that in none of the cases brought forward had a fracture been discovered after the skiagrams in the early stages had proved negative. He strongly recommended that in all cases of violent shock to the spine—such, for example, as

that following aeroplane crashes—very careful radiograms, both from the lateral and from the antero-posterior points of view, should be taken as a routine measure as soon as possible after the accident. If it is true that vertebral bodies shown radiographically to be unchanged immediately after an accident are apt none the less gradually to develop atrophic changes and to alter their shape, it is most desirable to produce in a series of cases a succession of radiograms showing how the various changes develop. Such an investigation might well occupy the attention of the medical officers of the Royal Air Force in the near future. So long as our knowledge of the pathology of minor injuries to the vertebrae is deficient treatment must be largely empirical; without a sure foundation in morbid anatomy we cannot even be certain of preventing the appearance of delayed lesions. Sir Percy Sargent and Dr. Morton Smart referred to the good results following electrical treatment to the muscles, the latter claiming that these results were sometimes due to breaking down adhesions by active muscular contraction. There can be no doubt that the muscles must be taken into account in the treatment of this type of injury no less than in the treatment of injuries to the limbs. Some of us are apt to regard a fracture as affecting the bone alone—an error in which we have perhaps been confirmed by the mere fact that muscles, like other soft parts, are generally not represented on *x*-ray plates. But in a spinal injury severe enough to cause crushing of a vertebral body, ligaments and muscles must suffer as well, and in devising means of treatment this fact should not be forgotten. In a leading article (December 17th, 1927, p. 1152) commenting on a discussion of the Section of Orthopaedics of the Royal Society of Medicine reported in the same issue (p. 1145), we referred to some work of Dr. R. B. Osgood of Boston on the subject of fracture of the spine. Dr. Osgood, basing his conclusions on a survey of 242 cases, maintained that following industrial and motor accidents there frequently occurred undetected compression fractures which, left untreated, might lead to a train of late symptoms similar to those described by Group-Captain Wells. Support for the vertebra by means of a suitable brace (such as that mentioned by Sir Percy Sargent) would prevent development of late symptoms in most, if not in all, cases, and yet permit the wearer to follow even an active occupation. The discussion on Group-Captain Wells's paper may perhaps seem somewhat negative and inconclusive; it should none the less help to direct attention to a gap which requires filling in our pathological knowledge, and, above all, to the paramount necessity of taking efficient radiograms of every case in which, from the nature or violence of the accident, the spinal column may have suffered injury.

THE MAYOS.

THE name of Mayo, so honoured in our profession to-day, has long held a distinguished place in the history of science. John Mayouwe, Mayow, or Mayo, one of the pioneers of physiology in the second half of the seventeenth century, died in 1679 at the age of 35; until the appearance of Priestley and Lavoisier there was no one worthy to take his place in the field of physiological chemistry. His memory is one of the glories of English medicine. He left no offspring, and we do not know whether any of the medical Mayos of the eighteenth and nineteenth centuries could claim to be his kin. It is a remarkable fact that of the fourteen Mayos commemorated in the *Dictionary of National Biography* six were medical men. Four belonged to an old Hertfordshire family, and of these two were physicians and one was a surgeon to the Middlesex Hospital, and the other, Thomas Mayo, was President of the Royal College of Physicians in the period 1857–62. Herbert Mayo, surgeon and physiologist, was a prominent figure a hundred years ago; he is remembered not only for his professional attainments, but for his success in a bitter controversy with Sir Charles Bell on the question of the nerve supply to the muscles of the face. The honoured name of Mayo was carried across the Atlantic by William Worrell Mayo, who, after receiving his medical education in Manchester, went as a pioneer into what was then the wilderness of Minnesota; there, in Rochester, he founded the St. Mary's Hospital, to the direction of which his two distinguished sons succeeded. It is unnecessary to dwell on the wonderful organization which has made the names of the brothers Mayo and their skill famous throughout the world. We learn with great pleasure that both of them, forsaking one of their own precedents, will visit Manchester next July to take part in the Annual Meeting of the British Medical Association. We venture to believe that William and Charles Mayo will receive not only a warm welcome from the Association, but all the honour which Manchester can pay to the celebrated sons of one of her own alumni.

THE EPIDEMIOLOGY OF LEPROSY IN AUSTRALIA.

A REPORT on *The Epidemiology of Leprosy in Australia*,[1] by Dr. Cecil Cook, Wandsworth Research Scholar, 1923–25, of the London School of Tropical Medicine, gives us in some 300 pages a very detailed account of the prevalence of leprosy, with tables of cases, together with much theoretical discussion and a good deal of repetition of the arguments used. The more important facts brought out by a painstaking inquiry include strong evidence that leprosy was probably unknown among the Australian aborigines before the introduction of the disease by coloured immigrants, such as Chinese, especially in the Northern and Western Territories and in Victoria and the southern parts of New South Wales; another route of infection was through the South Sea Islanders, or Kanakas, so largely employed formerly, and to a less extent at the present time, on the Queensland sugar plantations. Owing to the great excess of males these coloured aliens cohabited with and infected the aboriginal tribes of Australia, and they in their turn communicated leprosy to the white population in areas and at times when the white males greatly exceeded in number the females, as indicated by the great bulk of the cases occurring in adult males, especially in agricultural districts. Later the disease spread among the domesticated whites, when females and juveniles formed the majority of the infections, indicating the usual type of household infections, which still persists, especially in Queensland, and, to a less extent, in New South Wales. In the sparsely inhabited Northern Territory the disease died down with the disappearance of the great majority of the aboriginals, and in Victoria the white races have never been infected, because the aboriginal tribes had practically disappeared before the introduction of leprosy by Chinese with the opening up of the goldfields; for there was not sufficient social intercourse between the Chinese and the white races to allow of infection of the latter. At one time the author was inclined to think that the rat might be an intermediate host of leprosy, and that infection might be transmitted by the rat flea, *X. cheopis*, but further experience brought him into agreement with the general view that the disease is slowly contagious through prolonged close personal contact. The incidence of the disease confirms in a striking manner the relationship of high humidity to high leprosy rates, mostly of the infective nodular type in the damp coastal area, and with few nerve cases in the dry and elevated interior. The uninfective nature of many nerve cases is recognized, but apparently they also are segregated. Australia presents an interesting field for the study of the effects of

[1] *The Epidemiology of Leprosy in Australia.* By Cecil Cook, M.B., Ch.M.Syd., D.T.M. and H. Commonwealth of Australia, Department of Health, Service Publication, No. 38. Canberra: H. J. Green. (6 × 9½, pp. 305; illustrated.)

thirty years' stringent legal compulsory notification and segregation. In New South Wales Dr. Cook considers that the disease is now well under control, as no new cases have been found during the last few years, but no figures or diagrams are given in support of this statement. On the other hand, diagrams are included in support of his conclusion that "in Queensland it appears to be gaining ground in spite of an apparently identical prophylactic system" as in New South Wales. Nevertheless he considers that "lazaret isolation is, therefore, the prophylactic measure *par excellence*." The better results in New South Wales are attributed to the disease being more domesticated there, and to the early good work of Ashburton Thompson, while in Queensland some cases are hidden and there is insufficient control of contacts and discharged patients. Moreover, no provision is made for the treatment of early bacteriologically negative cases—just those which respond best. The average duration of the disease on first detection is not recorded, but elsewhere it persists for four or more years, and this accounts for the comparative failure of rigid isolation. The most important of Dr. Cook's recommendations is the adoption of the plan, previously advocated in the work on leprosy of Rogers and Muir, to examine all contacts of known lepers every six months for five years in order to detect and treat the early infections. He thinks also that the treatment in the lazarets requires to be improved.

MONKEYS AND HUMAN DISEASE.

THE position of the monkey and his relations in the evolutionary scheme has always been a subject of speculation and interest to every class of student. His near relationship to man is now generally admitted; how near is that relationship was disclosed at a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine held on February 7th, when "Monkeys and human disease" formed the topic for discussion. The anatomical relationship between man, apes, and monkeys was epitomized by Mr. R. I. Pocock, F.R.S., late superintendent of the London Zoological Gardens. He pointed out that one of the most marked differences between true monkeys and apes is seen in their mode of locomotion. On the ground the monkey is a quadruped, the ape a biped, especially when young; in the trees monkeys are good climbers and jumpers, jumping for the top of a branch, while apes are poorish climbers, and jump for the under side of a branch. In fact, there is some evidence to suggest that the ape's arboreal activities are a secondarily acquired character—induced perhaps by pressure from his highest relation. Mr. Pocock considers that the most significant difference between man and other primates lies in the foot, and that man left the simian stem in relatively early evolutionary times. The other speakers considered this relationship from the point of view of disease. Mr. Lovell showed that many of the intestinal conditions of monkeys in captivity were caused by organisms found also in man. As in man, tuberculosis was a very common condition; however, there was a slight difference, in that monkeys were almost equally susceptible to both strains of mammalian bacillus, though deaths from tuberculosis were mainly due to the human variety. Little is known about the virus diseases of monkeys, but, as Dr. E. Hindle said, only in primates was it possible experimentally to develop yellow fever, poliomyelitis, and perhaps measles. Other human virus infections can, of course, be transmitted to them, but in these three diseases the monkey appears to be the only alternative host to man. Among the internal parasites virtually all the protozoa of man are found in apes or monkeys, but it appears to be possible that the malarias of man are biologically distinct from those of apes. The story is a different one with the worms, however. With the exception of the schistosomes practically none of the characteristic human worms occur in other primates. Accidental interchanges do occur, and in parts of Africa monkey forms quite frequently appear in man; but on the whole their faunas are distinct. An interesting evolutionary point was made by Dr. T. W. M. Cameron in connexion with pinworms. The method of spread of these parasites is by personal contact, and this tends to limit the various species of parasite to the same host. Now pinworms occur in monkeys, and all the forms in primates belong to the same genus. The species in monkeys, however, are different from the human, and the more distant the relationships between the hosts the greater are the differences between the parasites. A somewhat similar state of affairs among the lice was pointed out by Dr. V. B. Wigglesworth. The family containing the human lice is limited to the primates; the genus in man is found only in apes, while that in monkeys is a different genus. The crab louse—the third member of the family—is only found on man and the gorilla. The evidence of the part played by apes and monkeys in the spread of human disease was, on the whole, reassuring; they may, however, as has been suggested in these columns (December 29th, 1928, p. 1184), play an important part in the spread of bilharzia disease, and it is just possible that they act as reservoir hosts for yellow fever. Dr. Andrew Balfour drew attention to the fact that in South America epidemics in monkeys of what might have been yellow fever often preceded epidemics in man of what certainly was yellow fever. The evidence, however, is still inconclusive. Certainly here, and in some other conditions, the monkey has been an essential laboratory aid, but to the hygienist his significance is relatively slight. In fact, as Professor Leiper pointed out, such of man's diseases as are common to him and the lower animals result from food habits and contact; and domestication is a much more important factor than blood relationship.

PAUL UNNA.

By the death of Paul Gersen Unna in his seventy-ninth year a noble figure and a great leader has been lost to dermatology. It is no exaggeration to say that Unna has done more than any other single person for the advancement of the specialty to which he devoted his long life, and to which he has been faithful right up to the end. Never has he ceased from work and research. It was only within the last few months that he published his *Histochemie der Haut*, a volume which showed that the flight of time had in no way impaired his scientific ardour or acumen. Unna was born on September 8th, 1850, of a Hamburg family with strong medical traditions extending back some two hundred years. After a general education in his native town he commenced his medical studies in Heidelberg in 1870, but they were interrupted almost at once by the outbreak of the Franco-Prussian war, for which he immediately volunteered, and in which he was dangerously wounded in the leg. Subsequently he studied in Heidelberg, Leipzig, and Strasbourg, where in 1875 he submitted for his doctor's degree a thesis on the development of the skin. This thesis was only accepted after a struggle with von Recklinghausen, who objected to it on the ground that staining reactions, on which [illegible] argument depended, were insufficient evidence for scientific conclusions. With the help, however, of Waldeyer, Unna obtained his degree, and the revolutionary ideas first enunciated in that thesis have formed the basis of a great part of his subsequent researches, even up to the recently published *Histochemie*. Unlike most of the leading figures of German medicine, Unna did not become associated with any university until very late in life. His whole professional life was spent in his native city, where he started as an assistant to his father in general [illegible]

in 1878. From the very first he specialized in dermatology, with such success, indeed, that in 1881 he founded a clinic of his own, which in course of years grew into a very large institution. In 1882 he began the publication of a periodical devoted to dermatology, now widely known as the *Dermatologische Wochenschrift*, and it is in its pages that most of his papers have been published. Already in these early years Unna had made professional pilgrimages to foreign countries, where he became acquainted with other dermatologists. He had considerable social qualities, and the connexions so formed became of importance in after-life. The chief objects of his research during this time were leprosy, which he had seen in Norway with Hansen, and, as always, the staining reactions of the skin as a guide to the understanding of its chemistry and biology. It is a curious thing that Unna's reputation grew much more quickly in foreign countries than in his native land. He was held in particularly high esteem among British dermatologists; after his first appearance at a meeting of the British Medical Association in 1887 he was invited almost every year to take part, and his travels were extended as far as the United States of America. Partly as a consequence of his journeys, he brought out, in conjunction with the late Sir Malcolm Morris and others, the *International Atlas of Rare Diseases*. In 1890 he first described plasma cells, which were then received with great scepticism, especially by Neisser and his pupils, with whom Unna was usually in conflict, but which are now one of the best-known kind of cell in pathology. In 1897 began to appear the famous *Atlas of the Pathological Histology of the Skin*, to be completed in 1910 in nine volumes. About the same period much of Unna's attention was directed to the problem of eczema, which he thought that he had solved by the discovery of a microbe which he designated the morococcus. His work on this subject, however, has not been confirmed by subsequent workers, and we believe that ultimately Unna himself receded from the position he had taken up. These subjects by no means exhaust the tale of his activities; every branch of dermatology was touched by him, and he made particularly important contributions to therapeutics, on which he published a textbook. It will be remembered that he introduced ichthyol to the profession. Meanwhile, the activities of Unna had attracted many students of dermatology to Hamburg, which, although not a university, gradually became a great centre of dermatological education, and the master gathered round him a distinguished corps of assistants. In 1900, when the new University of Hamburg was barely visualized, Unna was already giving a complete course of instruction in his subject. In 1907 he was accorded the title of professor, but it was not until 1919 that the university was actually inaugurated, and Unna, in his sixty-ninth year, became professor of a university in being. Unna was never particularly keen on practice for its own sake. With his reputation as a master in his department he could not help attracting a vast and remunerative clientele, but as the years passed by he relegated it more and more to his capable assistants, among whom his three sons were conspicuous, and devoted his energies increasingly to his favourite subject, the biochemistry and histochemistry of the skin. This semi-retirement was interrupted by the war. It bereft him of all helpers except his daughter-in-law, Dr. Marie Unna, and the veteran Dr. Leistikow, but it found his energies unimpaired. All difficulties of private and hospital practice were overcome, and he even found time to impart to a wearied nation the fruit of forty years of experience, the war aphorisms of a dermatologist. That was ten years ago; since then he has continued to work with all the old industry and application. What that means is shown by the mere list of papers written by him. During his sixty years of active professional life Unna produced over six hundred publications dealing with every aspect of his subject. It is quite impossible to describe their variety. He has died in harness.

PUBLIC ELEMENTARY EDUCATION.

In their announcements of forthcoming publications, and in those statements which sometimes accompany volumes sent for review, publishers may be taken to set forth what they believe to be the value of a book and the aims and intentions of its author. On examination, however, the claims thus made are not always justified. A case in point is the volume entitled *Mass Education in England*,[1] by Dr. J. H. Garrett. The publishers regard this as "a very important book, an informed and trenchant criticism of public elementary education with some startling information and deductions." In this book, they say, the author "sets out to prove the fallacy of proposing an equal education for all children irrespective of their varying individual educability and the nature of their after-employment. He shows the waste in teaching effort and public expense entailed in the present system, and the irrational enthusiasm that proposes further effort and expense by extension on the same lines." It may, however, be fairer to take Dr. Garrett's own statements rather than those of his publishers. At the outset the author makes two main propositions. The first is that "little thought has been directed to the varying mental qualities of the scholars and the difference of treatment required in the case of one and another to accord with the comparative ease and difficulty of learning, or of being taught, which they display, and to the failure as well as the success that is inevitable in school education. The human material to be educated has been treated as if it were all equally teachable." On the contrary, this individual variation of mental power and educational need has been the chief subject to which teachers and administrators, in general, have directed their attention for many years past. The success of different schools and authorities in dealing with the problems has no doubt been unequal, but, on the whole, it has been considerable; and the fundamental proposals of the Consultative Committee to the Board of Education, which Dr. Garrett so roundly condemns, are all directed to making greatly increased provision for these varying individual needs. The author's second proposition is that "for the main part of the populace the young person has no immediate chance of choosing his occupation. By far the greater part of active human labour concerns employments of a mechanical or simple nature, requiring no great mental endowment. These simpler employments actually prevent the application of the knowledge acquired in schools, which is consequently soon forgotten, the whole effect of the school effort being lost and wasted, sometimes entirely, sometimes in part." The school education of the majority of children ought, therefore, to be not extended, but curtailed. Dr. Garrett's argument on these two propositions is as follows. The majority of children are of very limited mental capacity; those whose capacity is definitely superior can soon be picked out, and may properly receive a wider instruction than the others; in all cases the overwhelmingly predominant aim must be to give just so much instruction as will enable the child to earn a livelihood. Thus, any instruction beyond reading, writing, and the simpler operations of arithmetic is sheer waste, as the great majority of pupils will perforce be engaged in very simple occupations. Instruction in manual work, in domestic subjects, or even the more directly occupational teaching in technical schools is also sheer waste, as these things can be picked up better in the course of practical experience outside the school. This being so, in

[1] *Mass Education in England*. By J. H. Garrett, M.D. London and Cheltenham: Ed. J. Burrow and Co., Ltd. 1928. (Cr. 8vo, pp 133. 3s. 6d. net.)

the great majority of cases there is no need for a teacher to have appreciably more knowledge than is needed by the pupil. An ability to impart knowledge is necessary for a teacher, but this ability is inherent and cannot be taught. Therefore all training of teachers, and almost all superior education of teachers, is, again, sheer waste of public money and of individual effort. Such are the ideas evolving from Dr. Garrett's critical examination of the problem of mass education in England. They are very old ideas. Year by year they have been becoming increasingly obsolescent, so that now it is a surprise to have this demonstration that they are not yet quite obsolete. Yet there is one educational problem, becoming rapidly more insistent of solution, which, if it does not emerge from Dr. Garrett's logic, underlies his thought. When, at 11 years of age or so, all those elementary school children who have passed a proper test of fitness for further school education are appropriately dealt with, and when, on the other hand, mentally defective children and those who are very backward have already been catered for, what exactly should be done for the remainder? Among them will certainly be a relatively small number of late developers who at 13 or 14 years of age will be found to be as worthy of further school opportunity as some of those who had been previously selected. But what of the rest? What exactly is the character of the education they should receive so that they may increase in knowledge to the extent of their capacity, and their mental habits and social behaviour may continue to be influenced for good? Neither teachers nor education administrators have, as yet, fully thought out this difficult problem.

A MEDICAL UTOPIA.

IN the February number of the *North American Review* Dr. G. W. Haigh, writing under the heading of "State medicine: boon or bogy?" proposes that the medical and surgical system of the United States Navy should be the model for a State or national service for the whole nation. In his opinion the time has come for serious consideration of the institution of State service, and by State medicine he means "not a service retaining all the deficiencies of the individualistic competitive form of medical practice, such as the panel system of Great Britain or the sickness societies of Germany, but an organization based upon the economic principle of the division of labour and designed to insure co-operation in supplying a public necessity; to wit, a complete, free, in time compulsory health and accident service maintained by each commonwealth." This proposition, he holds, is not more socialistic than is the provision of education for all children; further, whereas education concerns a part of the people for a part only of their lives, health concerns all the people all their lives. Such a public service the medical profession has failed to supply at a reasonable cost, and it therefore behoves the people to supply for themselves the necessary organization. This he admits would entail acceptance of the official medical man, and would do away with choice of doctor. The people, he argues, would benefit, and so would the medical profession, who would form a corps into which all newly qualified men would enter, and be stimulated rather than stultified by so doing. After about five years' work in a position analogous to that of house-officers they would be eligible to choose a specialty. As a rule older medical men would not be obliged to continue to do work which has ceased to interest them, and which they did just as well or better earlier in their career. Medical officers of higher ranks would be relieved also of emergency and night work, so as to be better able to perform their duties of supervision, teaching, and administration. Some glaring evils of competitive medicine would also be eliminated by systematic co-operation; thus overwork and overfatigue, leading to hurry, carelessness, and mistakes, would disappear. Dr. Haigh, in short, looks with favour on the idea of a regimented State medical service. Most of us in this country would prefer to look for other ways of remedying the evils of competitive medicine.

THE WINNIPEG MEETING IN 1930.

As all the business of the Scientific Sections at the Winnipeg meeting of the British Medical Association, which begins on Tuesday, August 26th, 1930, will have to be arranged by correspondence, it is essential that its organization should be set on foot in good time. To this end the Council of the Association has appointed an Arrangements Committee, which will shortly proceed with the nomination of officers for the Sections, in each of which the Canadian Medical Association has nominated two vice-presidents and one secretary, leaving the Council in London to fill the remaining offices, including those of all presidents of Sections. The work of the Arrangements Committee will be materially assisted if it has before it the names of members of the Association who propose to attend the Winnipeg meeting, and the Medical Secretary will be glad to receive this information from those who are interested in the work of the Sections as soon as possible. It is, of course, too early to ask that members should now commit themselves definitely to attendance at the meeting; this request for names has no relation to the provision of transport, but is made solely to facilitate the work of the Arrangements Committee.

ROYAL COLLEGE OF PHYSICIANS.

THE Milroy Lectures before the Royal College of Physicians of London, on "Past and present diphtheria in England and Wales, with special reference to the London metropolis," will be given by Dr. J. Graham Forbes on February 26th and 28th and March 5th. Professor E. B. Verney will deliver the Goulstonian Lectures on "Polyuria" on March 7th, 12th, and 14th. The Lumleian Lectures, entitled "A medical review of the surgery of the chest," will be given by Dr. R. A. Young on March 19th, 21st, and 26th. Dr. F. M. R. Walshe will deliver the Oliver-Sharpey Lectures on "The physiological analysis of some clinically observed disorders of movement" on April 30th and May 2nd, and the Croonian Lectures, on "Some chemical factors in the control of the circulation," will be given by Dr. H. H. Dale, F.R.S., on June 4th, 6th, and 11th. The lectures will all be given at 5 p.m. at the College, Pall Mall East.

INFLUENZA.

As we anticipated last week, there has been a considerable increase in the number of deaths attributed to influenza, and it does not seem likely that the maximum has yet been reached. Last week's statistics again showed a disproportionately large increase in the recorded incidence of primary pneumonia in comparison with the number of deaths assigned to influenza, and there is still a consensus of opinion in clinical reports from the affected areas that the type of the disease is mild. There seems at present to be a concentration upon the north-western districts of England and the southern ports or coast towns. The great industrial centres of Yorkshire and the Midlands are less affected. The age distribution of the deaths is of the normal inter-pandemic type.

No. 125 of the Special Report Series, issued by the Medical Research Council, comprises *A Study of Intracranial Surgery*, by Mr. Hugh Cairns, F.R.C.S. It deals largely with work in Professor Harvey Cushing's clinic at Boston, where the author acted as resident assistant surgeon while holding a Rockefeller Travelling Fellowship. We hope to discuss this report in a later issue.

THE KING.

It was announced on Friday, February 8th, that a radiogram taken that morning confirmed the clinical evidence that the condition of the lungs was now normal, and that, weather permitting, His Majesty would leave Buckingham Palace next day for Craigweil House, near Bognor. The journey through Surrey and Sussex by motor ambulance was borne very well, and, notwithstanding the severe weather of the past few days, further improvement has been noted in the King's condition since his arrival. The change to the sea coast is evidently doing good.

THE KING'S AMBULANCE.

From the point of view of the doctor particular interest attaches to the construction of the motor ambulance chosen for His Majesty's journey from Buckingham Palace to Craigweil House. The body of the ambulance was specially designed by Mann Egerton and Co. Ltd., of Norwich and

Interior of Motor Ambulance.

London, consulting engineers to the Medical Insurance Agency, and built by them on to a 45-h.p. Daimler chassis. The bed, which is placed on the right, is made to slide in and out of the car; should the need arise it can be turned about without disturbing the patient. For those in immediate attendance on the patient there is an armchair on the left at the head of the bed, and at the foot an upholstered seat. A dark green carpet covers the floor; there are three large windows fitted with blinds, and there are two electric lights. By means of a special electric heating apparatus and an electric fan the temperature inside the ambulance can be regulated at will. A mahogany and nickel hand-basin is supplied with water from a tank. A single swing-door, with glazed window, gives access from the back of the car. Exhaustive tests had proved this ambulance to be capable of carrying the patient in comfort while maintaining a high average speed. The accompanying illustration shows the interior as seen from behind. These ambulances are supplied by the Daimler Hire Company, of Knightsbridge, S.W.

MEDICAL TEACHING AND RESEARCH IN SHANGHAI.

The Henry Lester Institute.

A scheme which should have an important bearing on medical research and education in the Far East has recently been launched in Shanghai. An Englishman, Mr. Henry Lester, who had spent the greater part of a long life as an architect and estate agent in Shanghai, died in 1927, and, by a will executed two years prior to his death, bequeathed the bulk of his large fortune to various schemes for the promotion of education, along British lines, amongst the Chinese of the city of his adoption. After the disbursement of certain specified legacies covering various medical and educational institutions in Shanghai, the residue of the estate is placed under the control of "The Lester Trust" in order to give effect to the directions of the testator. The trustees must always be British subjects ordinarily resident in Shanghai.

The clause in the will which will be of most interest to the medical profession is that dealing with "the establishment of an institute or institutes for the study of and instruction in the English language, of medical science, surgery, civil engineering, architecture, and other useful and scientific knowledge." The trustees have decided to separate medical science from the purely technical subjects, and to proceed at once with the erection of a dignified building, equipped on the most modern lines, for research in medicine and surgery. Dr. H. G. Earle, formerly professor of physiology in the University of Hong-Kong, has been appointed as general adviser to the trust.

Directions are given that the institute "be open to all nationalities, but especially Chinese," that not less than Shanghai taels 400,000 (over £50,000) should be expended on the building and equipment, and that it "be known as the 'Henry Lester Institute' and by no other name." The total amount of the residuary estate is still unknown, but, when all the other bequests have been provided for, it is expected that there will be funds amply sufficient to staff and endow a school containing at least six main divisions. These divisions will comprise:

1. Medicine, including Tropical Medicine and Parasitology.
2. Pathology, including Bacteriology and Immunology.
3. Physiology, including Biochemistry, Pharmacology, and Industrial Physiology.
4. Surgery, including Experimental Physiology.
5. Hygiene and Public Health.
6. Field Research and Statistics.

The heads of divisions are at present being recruited from British schools of medicine, and it is hoped that the junior posts will be largely filled by young Chinese who have been trained abroad.

Until the institute is built, equipped, and organized, the activities of the staff will be entirely confined to research; later on, it will be possible to initiate curricula for post-graduate studies in public health, tropical medicine, and surgery, and in the event of the institute becoming affiliated to the University of Hong-Kong, there will be no further necessity for Chinese students to travel thousands of miles in order to take the D.P.H. or D.T.M.

The Lester Chinese Hospital.

Another medical institution which will benefit by Mr. Lester's generosity is the Chinese Hospital, long associated with the London Missionary Society, situated in Shantung Road, at a distance of about a mile from the proposed site of the institute. The bequest of Shanghai taels 1,000,000 (£130,000), together with certain valuable properties, will be sufficient to rebuild and partly endow a hospital with accommodation for about 200 patients. The new building will be known as "The Lester Chinese Hospital," and it will be controlled, not by the Lester Trust, but by its present board of trustees. It would obviously be to the advantage of both institutions if the clinical facilities of the hospital could be utilized by the research staff of the institute, and a beginning has been made by the appointment of Dr. Gordon Thomson, F.R.C.S., head of the division of surgery in the Lester Institute, as honorary visiting surgeon to the Chinese Hospital. The public health authorities of the Shanghai

Municipal Council have also agreed to place facilities for the collection of material at the disposal of the institute.

The Lester benefaction is a sign of the times. Business and professional men who have settled and succeeded in China are not all anxious to gather their fortunes together and return to their native shores. To those who have lived longest among the Chinese the medical, educational, and social needs of the country make a strong appeal, and foreign benefactors are beginning to find that they can "cast their bread upon the waters" with confidence.

MEDICAL MEMBERS OF LOCAL PUBLIC BODIES.

A REQUEST was made in the *British Medical Journal* some months ago for the names of medical practitioners known to be serving as members of local authorities or their subsidiary public bodies in Great Britain with the object of placing this information at the disposal of the profession generally and thus facilitating co-operation among medical men in public affairs. In view of the fact that the Local Government Bills now before Parliament will be followed by extensive changes in public health organization and administration such co-operation is now more desirable than ever. The two lists of names already published—on December 8th (p. 1057) and December 29th, 1928 (p. 1190)—gave details relating to about 125 authorities in all. The following is a supplementary list of names received too late for inclusion in the earlier lists.

ENGLAND AND WALES.

COUNTY COUNCILS.

Derbyshire.—Dr. W. T. Wood, Creswell (Member of the Education, Tuberculosis, Maternity and Child Welfare, Mental Deficiency, and Blind Persons Act Committees).

Montgomeryshire.—Dr. W. H. Lewis, Llansantffraid (Chairman of the Public Health, Maternity and Child Welfare, etc., Committees; Member of the Education and Mental Deficiency Committees).

West Riding of Yorkshire.—Co-opted member of Tuberculosis, etc., Subcommittees: Dr. G. B. Hillman, Wakefield.

West Sussex.—Dr. Sidney Matthews, Crawley (Alderman; Chairman of the Public Health, Midwives, Maternity and Child Welfare, etc., Committees).

COUNTY BOROUGH COUNCILS.

Rochdale.—Dr. Daniel Richmond (Alderman; Member of the Health Committee), Dr. John Rodley (Alderman), Dr. James Melvin (Member of the Health Committee), Dr. H. G. Ramsbottom, and Dr. E. H. S. Scarr.

Wakefield.—Dr. G. B. Hillman (Chairman of the General Purposes Committee; Member of the Health, Maternity and Child Welfare, etc., Committees).

NON-COUNTY BOROUGH COUNCIL.

Hereford.—Dr. J. R. Bulman (Member of the Health, Education, etc., Committees), and Dr. J. A. Pritchard (Member of the Health, etc., Committees).

METROPOLITAN BOROUGH COUNCILS.

Hampstead.—Dr. E. Collingwood Andrews, Heath Drive, N.W.3 (Deputy Mayor), Dr. C. W. Cunnington, West End Lane, N.W.3 (Alderman), Dr. W. S. George, Finchley Road, N.W.3, and Dr. C. J. R. MacFadden, Frognal, N.W.3 (Chairman of the Public Health Committee).

Islington.—Co-opted member of the Maternity and Child Welfare Subcommittee: Dr. Eleanor Pulleine, Hamilton Terrace, N.W.8.

Westminster.—Dr. H. W. J. Steen, Warwick Square, S.W.1 (Member of the Public Health Committee).

URBAN DISTRICT COUNCIL.

Harpenden (Herts).—Dr. A. L. Hine (Vice-Chairman; Chairman, Joint Hospital Committee for St. Albans and Harpenden Urban and Rural Districts).

BOARD OF GUARDIANS.

Hampstead (London).—Dr. Mary B. Douie, Heath Hurst Road, N.W.3.

PARISH COUNCIL.

Elmton-cum-Creswell (Derbyshire).—Dr. W. T. Wood, Creswell.

SCOTLAND.

TOWN COUNCILS.

Edinburgh.—Dr. G. F. Barbour Simpson, Manor Place.

Glasgow.—Dr. James Dunlop, Dennistoun (Bailie), Dr. James Dunlop, Shettleston, Dr. Simon H. Bennett, Windsor Terrace, and Dr. Robert Forgan, Renfield Street.

Union of South Africa.

Notification of Measles in Pretoria.

DR. J. J. BOYD, who is medical officer for Pretoria, recently delivered an interesting address to the Medical Association of South Africa (B.M.A.) on the epidemiology of measles and the local preventive measures which were in force. The address was published in the *Journal of the Medical Association of South Africa* (*B.M.A.*) of December 8th, 1928. This disease is endemic in Pretoria, and for over twenty years has been notifiable in respect of the first case in a household. Dr. Boyd remarked that in most places where notification of measles had been tried it had been given up as not worth while. One of the chief arguments against it was that it was too incomplete to give any useful information as to the occurrence and distribution of the disease; a very large proportion of cases was not seen by any medical practitioner, and the parents did not report cases to any considerable extent. In Pretoria, however, a different state of things had prevailed, at least as regards the European population. Dr. Boyd was satisfied that very few cases escaped notification; measles was more readily recognized by the laity than most other infections, and about one-fifth of the cases were reported by lay persons. Another criticism raised had been that cases were reported so late in the course of the illness—not until the appearance of the rash—that action by the health department was too late to prevent the spread of the disease. While admitting that no course of action, other than serum inoculation, could prevent susceptible children who had already been in contact with the notified cases from developing the disease, Dr. Boyd said that its further extension could undoubtedly be effectually prevented if all the contacts were known and kept apart from susceptibles. Dealing with the objection that in epidemic time the number of cases became so great that the authorities could not cope with them, he said that he believed this referred to disinfection of premises, which he regarded as useless. A considerable amount of work was involved in the discovery and control of contacts, but if success followed the efforts of the health officials severe epidemic prevalence should be rare. This had been so in Pretoria in the last decade. The control of susceptible contacts was the crux of the matter so far as limitation of the spread of the disease was concerned, and the measures in use in Pretoria were chiefly aimed at such control. Dr. Boyd showed that in the twenty years from 1907 to 1927, while there had been comparatively little reduction in the average annual case-rate among children, the death rate had declined substantially; among children under 5 it was 1.38 per 1,000 in the quinquennium 1907–12, 2.25 in 1912–17, 0.29 in 1917–22, and 0.26 in 1922–27. A considerable fall in the death rate from measles among older children had also been recorded. Such a fall might be due to one or more of the following causes: to a lessened incidence of measles in children under 5, to greater care of children suffering from the disease, or to a reduced virulence of the disease. Since the introduction of notification great prominence had been given to the disease, and parents, recognizing the serious view of it taken by the health department, had been much more careful. In other South African towns the figures, in a number of cases, showed no striking decrease, and it appeared, therefore, that some factor other than a simple fall in virulence had probably come into play in the reduction of the death rate from measles and its sequels in Pretoria. Dr. Boyd said that he was the more inclined to attribute a considerable proportion of the fall to the adoption of notification and the control and supervision of cases when he found that similar results had followed the adoption of these procedures in certain other places.

Epizootic Among Rodents.

Plague has for many years been enzootic among the wild rodents of this country. Waves of the disease periodically pass over the country causing a very high mortality among the gerbilles which occur over the greater part of the Union. The area involved is too vast, and the popu-

population generally too sparse, to render efforts for the complete eradication of gerbilles practical. Rodent-free barriers have been thrown in front of epizootic waves at various parts of the country to prevent them reaching thickly populated areas. For some years such a barrier has been successfully maintained some two hundred miles north of Capetown between the coast and a range of mountains which runs parallel to it, mountainous regions being everywhere free of gerbilles. Apart from maintaining such rodent-free belts, the Government Health Department keeps a watchful eye on rodent health throughout the Union. Rodent surveys are continually being conducted by "rodent officers," and any unusual rodent mortality is immediately investigated. Such investigations sometimes reveal the fact that other organisms than *B. pestis* are responsible for extensive rodent mortality. Recently a very fatal epizootic occurred in the De Aar area, a region about five hundred miles inland, in which enzootic plague infection was known to have existed since 1925. Large numbers of gerbilles were reported as moving across the country, and it was at first supposed that they were fleeing before a wave of plague infection advancing from the west. Some of the animals appeared sick, and many were found dead. Departmental investigation showed that lay statements, that a vast army of rats was advancing on the town of De Aar, were exaggerated. Rodents had recently multiplied rapidly over an area extending some five to ten miles west of De Aar, and under the influence of the epizootic were invading the town in considerable numbers from that side. Many recently dead animals were picked up. These carcasses, however, do not remain lying on the veld long. Usually they are promptly picked up by white-breasted crows, which have flocked to the area in great numbers. Carcasses were examined bacterioscopically and inoculation tests made on healthy laboratory animals. Everything seemed to point to the condition from which the gerbilles were dying being plague, but the laboratory tests were inconclusive, and *B. pestis* could not be recovered.

Meanwhile, on a farm in Petrusville, to the north of De Aar, there occurred two fatal cases of plague, one of bubonic type, with terminal pneumonia, the other of pneumonic type. The diagnosis of these cases was confirmed by laboratory examination. The cases were attended, and later the *post-mortem* examinations performed, by Dr. D. M. Maciver, district surgeon of Petrusville. Shortly afterwards he became ill, showing a high temperature, and buboes formed in his right axilla. A provisional diagnosis of plague was made, and later confirmed. In the Government bulletin published on November 24th, 1928, his condition was reported to be improving, and by the beginning of December he was definitely convalescent. Localized mortality in veld rodents continued during December in De Aar and neighbouring districts, such as Victoria West and Kenhardt, but the results of laboratory investigations as to the cause of this mortality remained inconclusive. The deputy director of the South African Institute for Medical Research, who had been conducting the bacteriological examinations in Johannesburg, himself went into the affected areas to investigate the matter in conjunction with the officers of the Union Health Department. He collected material for further examination, and returned to the Institute to complete the investigations. Finally, it was definitely established that, though the human cases which occurred in Petrusville were certainly plague, the epizootic which was causing the heavy mortality in veld rodents in De Aar and neighbouring districts was not plague. An organism has since been isolated repeatedly from the heart blood and organs of dead gerbilles. This organism is Gram-negative, bipolar staining, and conforms morphologically and culturally to the Pasteurella group. It is capable of killing gerbilles, mice, and rabbits by scarification, and the same organism has been recovered from the organs of these dead animals. Moreover, the *post-mortem* appearances and the organism found in smears made from organs of healthy animals killed with this culture present a picture identical with that seen in gerbilles found dead in the De Aar district. It is very similar in its cultural and biological characteristics to *Pasteurella avicida*, the causative organism of fowl cholera. Further investigation is being carried out to establish or refute this. The Pasteurella group of organisms have frequently been responsible for epizootics among rodents in various parts of the world. As this organism is capable of killing gerbilles, rabbits, and mice on scarification, the scarification test, hitherto held to be diagnostic of plague, can now no longer be made on any of these animals. So far it has not been possible to kill guinea-pigs by scarification, but a certain percentage of guinea-pigs have been killed by subcutaneous inoculation and the organism again recovered from the organs. This is a further point in favour of scarification of guinea-pigs as the safer biological test for plague, but it is always advisable to confirm this test by parallel cultural reactions.

Pellagra in Durban Prisons.

In spite of the fact that the staple diet of the large Bantu population of the Union consists of maize or mealies, pellagra, which in other countries has been closely associated with such a diet, has been very rare in this country. This diet has often been productive of scurvy. When the native leaves his territories and commences hard work on the mines, the diet which met his needs in the kraal no longer suffices. His diet has to be supplemented with foods with a high vitamin C content. On most of the mines this is provided by a regular ration of germinated beans, vegetables, and meat. A comparable position with regard to pellagra now appears to have arisen in the prisons of Durban. Native prisoners who on admission to gaol are free from symptoms are liable to develop pellagra under prison conditions, which include a deficient, monotonous diet and hard labour, often on harbour work in the blazing sun. Careful Government and other inquiries over many years have shown the almost entire absence of pellagra from the Union outside Natal. Only five cases have ever been recorded from any of the other provinces. In Natal the history of pellagra has been interesting. During the Zulu rebellion of 1906 some 3,000 prisoners were taken. Dr. L. G. Haydon, who was in medical charge, picked out from among them about 150 typical pellagrins. The bulk of these prisoners had, by force of circumstances, been detained in batches in different parts of the country under more or less unfavourable conditions of food and housing, previous to their concentration at a station under Dr. Haydon's medical charge. During the progress of the rebellion it is probable that the majority of the native rebels in the field had to subsist almost entirely on an inferior quality of mealies. Between this occurrence and 1927 only five cases of pellagra appear to have been diagnosed in Natal. Attention was directed to the disease at the end of 1927, when seven pellagrins were discovered in the three Durban prisons. It then appeared that cases among natives, particularly in Northern Natal (which is still referred to as Zululand) were not uncommon, but the condition had not been recognized.

The outbreak in the prisons continued throughout 1928. Between December, 1927, and March, 1928, there occurred thirty-eight cases, but two of these were suffering from pellagra on admission to gaol. At this stage the Durban gaol diet for short-sentence prisoners, among whom most of the cases were occurring, was supplemented. Five more cases occurred in April, but during the three winter months there were only two new cases. During the following three months fourteen more cases occurred. In December there was only one, and none have occurred during January, 1929. Prison authorities are in a difficult position. On the one hand they are not infrequently accused of pampering the native prisoners, who probably receive in the prison a diet considerably better than they are accustomed to in their kraals; on the other hand the minimal requirements for maintaining health are an economic necessity. The precise dietetic deficiency which produces pellagra has not yet been established, and it is probable that other factors than diet are contributory, such as work in intense sunlight. In these circumstances the prison authorities would appear to be faced by the necessity for providing an almost luxurious prison

diet and less labour. Fortunately for them contributory conditions for the production of pellagra occur only in the one province of Natal; for with the same diet scales throughout the Union only one case has been recorded in a prison outside Natal. It is therefore only in this province that a supplemented diet has become necessary.

The present tailing-off of the outbreak may be associated with the introduction during November of a ration of good white beans for all prisoners. The matter is being investigated by the Union Health Department, and is being considered along with a more general survey of health conditions in the native territories.

Rabies in South Africa.

Plague is not the only disease enzootic among the wild fauna of South Africa. There has long been a strong suspicion that rabies existed among the yellow mongoose in certain areas, and this has at last been confirmed by pathological examination. During the past eight years at least twelve human deaths occurred with symptoms indistinguishable from rabies, following some weeks after bites by mongoose, wild-cat, or dog. These cases occurred over widely scattered areas in the north of the Union and separated by considerable intervals of time. Most of the cases occurred in children on farms in remote localities and, as a rule, the facts were not brought to the knowledge of the Union Health Department until the victim was dead and buried. As soon as the Union Health Department became aware of any such case investigations were instituted, but until last month this invariably occurred too late to secure satisfactory pathological material; putrefactive organisms had taken possession of the brain and the biting animal had long since been buried or thrown into the bush, and its associates were lost sight of. After each occurrence the magistrate and other officials of the area were warned of the danger, but there was no recurrence, each successive case occurring in an area remote from the previous one, where the medical and police authorities were not on the alert, although annual health reports and other broadcast circulars had mentioned the danger and requested immediate notification to the department. However, last November two European boys in the Wolmaransstad district, south of Klerksdorp, were notified as suffering from rabies. One died on November 20th, and the other three days later. Each of these boys was about 12 years old, and had, on October 30th, been bitten on the fingers by a yellow mongoose, locally known as a red meercat (*Cynictis penicillata*), which they had attempted to catch. As in all previous similar experiences no particular notice was taken of the matter at the time. The yellow mongoose is fairly common on the veld and instances of children or adults being bitten by this animal are not unusual. On November 17th both boys developed pains in the affected hands, both showing typical symptoms of rabies, one considerably more rapidly than the other. *Post-mortem* material was rushed up to Johannesburg by motor car, and examinations were made there by the South African Institute for Medical Research, and in Pretoria by the Veterinary Research Laboratory. The immediate microscopic examination of the material at the Medical Research Institute gave negative results, but inoculation tests subsequently performed at the Institute and the Veterinary Research Laboratory proved, however, that the clinical diagnosis was correct. If infection among yellow mongoose is widespread, as all the collected evidence appears to indicate, it is difficult to account for the fact that no epizootic prevalence has occurred among dogs or other animals. The official Government bulletin suggests that the strain of infection may be one of low virulence or diffusibility; this aspect of the matter is being further investigated. The general public has been warned of the danger by bulletins in the daily press, and urged to take no avoidable risk of being bitten by any wild or domestic animal. Instructions as to cauterization and (should there be any suspicion that the biting animal was rabid) vaccine treatment have also been given. Supplies of antirabic vaccine are available at the Government Health Laboratory, Capetown, and at the South African Institute for Medical Research, Johannesburg.

England and Wales.

Rating of Voluntary Hospitals.

MUCH concern has been caused among administrators of voluntary hospitals in England and Wales by the effect of the reassessment of their properties under the Rating and Valuation Act, 1925. The general result has been to increase considerably the assessments, and therefore the rates, of the hospitals, and there has consequently arisen a movement to secure some measure of amelioration. This, it is suggested, might take the form either of the general de-rating of hospitals or of provision for their assessment on a preferential and uniform basis. In order to elucidate the precise effects of the change and to obtain a clear expression of the attitude of the hospitals, an inquiry was initiated some months ago by the Central Bureau of Hospital Information, which addressed, at the end of last November, a questionary to 679 voluntary hospitals in England and Wales. Replies from 221 hospitals, containing 45 per cent. of the total beds, were received by the end of the year, and an analysis of their contents has now been published by the bureau.[1] It is estimated that the effect of the revision will be to raise the average assessment per patient bed from £1.56 to £2.36, involving an increase in the aggregate annual rate burden of the provincial hospitals from £44,000 to £66,000. In a number of cases the hospitals had not, in replying to the bureau's questionary, yet learnt their revised assessments, and so were ignorant of the exact effect of the Act upon their position. Of the 221 hospitals making replies, 51 (mostly influenced by the circumstance mentioned above) did not express any opinion on the subject of joint action, while 3 were definitely opposed to it; of the remainder, who favoured joint action, 107 considered that the object in view should be to secure the de-rating of hospitals, and 60 held that the aim should be to obtain assessment on a preferential and uniform basis. The effect of de-rating would be to relieve the provincial voluntary hospitals of an annual payment of approximately £66,000, but the effect of assessment on a preferential and uniform basis would depend, of course, on the datum line selected; the adoption of this measure might involve an increased assessment in certain cases. The memorandum estimates, however, that an assessment based on the figure of £1 per patient bed would involve increases in 19 per cent. of the provincial hospitals, containing 12 per cent. of the total beds, so that with such a basis a large majority of the hospitals would be either unaffected or favourably affected. Accompanying the memorandum are several interesting summaries of information based upon the replies to the bureau's questionary, in which a most striking feature is the wide variation in the assessments per patient bed, both before and after revision. It is pointed out that in several cases where the new figures are high and have been accepted without appeal, the hospitals receive from the local authorities substantial subscriptions under the Public Health Act, 1925. Examples are given of the scales adopted by various local committees in accordance with the recommendations of the Central Valuation Committee, upon which to base assessments of all hospitals within their areas; they reveal an amazing lack of uniformity in the interpretation of these recommendations, and emphasize the need for a complete review of the system as it affects the hospitals. In one area the basic scale for hospital assessment is 7s. 6d. per patient and staff bed; in another it is £5 per patient and staff bed; in a third it is 25 per cent. of the surveyor's valuation. Several hospitals base the claim to preferential assessment on the ground that their work in a large measure directly relieves the rates, while others argue that they should, like the churches, be given total exemption. In some cases it has been stated that as the hospitals concerned have no beds for paying patients, they cannot expect de-rating in respect of such beds, and therefore favour preferential assessment. Several interesting precedents in support of the special claim of the hospitals are quoted. In Glasgow

[1] Memorandum No. 6: Central Bureau of Hospital Information, 19, Berkeley Street, London, W.1. Twelve copies, 2s. 6d. single copy 4d. post free.

under a local Act, it appears, all voluntary hospitals are exempt from municipal rates, and the corporation is now endeavouring to secure the extension of this privilege to cover education, poor, and lunacy rates. In Edinburgh voluntary hospitals are also free from the burden of municipal rates, while in Halifax the infirmary and other charities are charged 10 per cent. only of the amount chargeable on the full assessments. The memorandum deserves the consideration not only of those directly concerned with voluntary hospital administration, but also of all who, as ratepayers and electors, are ultimately responsible for the attitude of their agents—the local authorities—towards the hospitals.

A Hospital Staff Fund.

An interesting measure was adopted at the annual meeting of the North Walsham (Norfolk) Hospital Saturday and Sunday Fund on January 23rd, when it was decided to offer a grant of £40 to the local cottage hospital to form the nucleus of a staff fund, and thus assist in meeting the out-of-pocket expenses of medical practitioners giving their services to the hospital in an honorary capacity. Dr. C. H. W. Page, who presided at the meeting, explained the object of the grant, saying that the general public was not fully aware of what had happened in connexion with the hospitals. He pointed out that owing to the extension of the class who sought aid at the hospitals and the introduction of complex forms of treatment involving institutional attendance, a great deal of extra work had been put upon the doctors, work which they, on joining the staff, undertook to carry out free. Doctors were extraordinarily proud to give their services to the hospitals; they wished to continue to give that aid, but the public was a little forgetful in allowing additional work to be placed on them at the expense of their private practices. They had four doctors on the staff of the North Walsham Hospital, and several on the consulting staff. Occasionally they had to ask a consultant to attend, and if he did so he was expected to pay his own motoring expenses and to treat the patient free. He was, of course, actually out of pocket. The staff fund would be for the purpose of making some allowance for such expenses, and others as well as doctors who gave their services might be brought within its scope. On his suggestion, therefore, the committee of the fund recommended the members to ask the local hospital to accept £40 as a nucleus for such a staff fund.

Scotland.

Motor Accidents in Scotland.

THE question of hospital cases arising from motor accidents is raised in the annual report of the Aberdeen Royal Infirmary. It is pointed out that these differ from the ordinary cases in that many of the patients have no connexion with the districts served by the hospitals in which they are treated, and that many of them require much greater length of treatment than the ordinary surgical cases for which the hospitals were originally intended. It has been estimated that during the year 1927 approximately 26,000 in-patients and 39,000 out-patients were treated in the provincial voluntary hospitals as the result of motor accidents, and that their cost to the community was approximately £230,000, of which not more than £26,000 was received by the hospitals either from or on behalf of the patients. It is suggested that legislation is necessary to enable hospitals to recover the cost incurred and to bring about compulsory insurance by motorists against third-party risks.

Glasgow Royal Infirmary.

The annual report of the managers of the Glasgow Royal Infirmary shows that during the past year 16,488 patients were treated in the wards, the average daily number of patients in the Infirmary being 783.8, and the average period of residence per patient 17.4 days. Out-patients numbered 97,258, with a total attendance of 327,913. The ordinary revenue for the year was £87,815, and the total ordinary expenditure £122,178. Extraordinary receipts had amounted to £26,746, and as the total extraordinary payments totalled only £2,510 there was a surplus of extraordinary receipts of £24,236. On the year's working there was thus a shortage of £10,127, which has been debited to capital account, and for the first time in many years the Infirmary has required to borrow from the bank in order to enable it to carry on. Through the generosity of Mr. William C. Teacher of Cove, Dumbartonshire, who has given £10,000 for the purpose, a lectureship in bacteriology has been founded at the Infirmary.

Victoria Infirmary, Glasgow.

The annual report of the Victoria Infirmary, Glasgow, shows that during the past year the number of in-patients treated was 6,580. There were, in addition, 4,775 cases of minor surgical ailments treated as out-patients, and 1,277 for diseases of the nose and throat. In the electrical and x-ray departments the total number of attendances was 23,254, a daily average of 75. At the Bellahouston Dispensary, connected with the hospital, the number of attendances was 48,223. The expenditure, including not only that of the Infirmary, but also of the Bellahouston Dispensary and the Convalescent Home at Largs, for the year was £57,595, while the income derived from subscriptions was £27,563. The subscribed income, together with the revenue from investments, fell short of the expenditure by £8,835, which had to be made up from legacies and special donations. As the extraordinary income was insufficient to meet the extraordinary account, the sum of £22,464 was drawn from capital. The endowment fund of the hospital now amounts to £173,719, having been increased during the year by £19,901.

New Falkirk Infirmary.

At a meeting of Falkirk Dean of Guild Court on February 7th plans were approved for a new infirmary at Falkirk. The scheme is to cost £100,000 and is to provide at the outset a hospital of 152 beds, with capacity for extension. Twelve beds will be available for paying patients. In the maternity section twenty-four beds will be provided, and in the isolation block twelve beds. The two latter blocks will be managed in co-operation with the public health authorities of Falkirk, Grangemouth, and Denny burghs, and of the Eastern District Committee of Stirling County Council, by whom the capital outlay involved in their erection will be borne. The hospital has been so designed that the administrative accommodation provided and the arrangements for extension of wards will admit of a large and easy increase of capacity as the occasion demands.

Ireland.

Influenza in Dublin.

AT the suggestion of Dr. M. J. Russell, medical officer of health for the city of Dublin, most of the elementary schools in the metropolis have been closed to help to check the spread of influenza. Arrangements are being made to continue the distribution of free meals to the children. The number of deaths from influenza registered for the week ending February 2nd was thirteen, as compared with four for the preceding week, and one for the week before that. Of these thirteen deaths, five persons were over 70 years of age, one was 60, and the remainder were all adults except one, a child of 2 years. Among the precautionary measures taken is the circularizing by the Public Health Committee of places of entertainment in the city, urging care in carrying out all sanitary regulations and in the provision of adequate ventilation. Dr. Russell has pointed out that it would be a very serious thing for Dublin if influenza occurred in epidemic form, owing to the fact that more than a quarter of the population live in overcrowded one-room tenements, and that it is impossible in such circumstances to take the recognized measures necessary to combat the spread of the disease. He emphasizes the importance, in prevention of the disease, of efficient ventilation and good nourishing food, neither

of which can be secured by a large proportion of the people, in congested areas, who, from unemployment or other causes, are in a state of semi-starvation.

Down Mental Hospital.

In the report of his inspection of Down Mental Hospital, Northern Ireland, Dr. Patrick, of the Ministry of Home Affairs, states that at his inspection on December 5th, 1928, there were on the books of the institution the names of 766 patients. Of the deaths within the year, 50 per cent. were due to cardio-vascular disease, in some cases associated with other conditions; there were seven cases of tuberculous disease, and four of general paralysis. In 50 per cent. of the deaths post-mortem examinations were made. No cases of zymotic disease occurred. Eight serious casualties were recorded, four being fractures of bones, of which two were of the femur; one case was caused by the patient being pushed off a seat by another inmate, and the other by a fall during a struggle in a day-room. Three patients escaped, but were all brought back after a few hours' absence. Ninety-eight patients returned as epileptic and suicidal were kept under special observation. The report states that the appearance of the patients was satisfactory, and that no reasonable complaints were made. Over 57 per cent. of the patients were usefully employed, and there was ample provision for recreation and entertainment. The premises and offices were found to be clean and in good order in all respects; the workshops were satisfactory, and the work performed appeared to be excellent.

Correspondence.

ENLARGEMENT OF THE PROSTATE.

SIR,—I am obliged to Mr. Cyril A. R. Nitch for his kindly response (February 9th, p. 264) to my comment on his article on enlargement of the prostate. He dispels my doubts as to his actual procedure, and I understand now that he avoids the rectal finger in prostatectomy. My difficulty was pardonable, for he recommended Freyer's operation, in which it is essential to use a rectal finger.

For the method of haemostatic suture and ligature in suprapubic prostatectomy I should be the last to claim perfection; but my experience has been—and I do not think I am alone in this—that it is the most efficient method in use.

In regard to the necessity for exposure and inspection of the bladder base and prostatic cavity, it seems a pity to neglect a method so easily applied and so certain when the way for it has already been prepared by a long incision. I do not myself feel safe unless I have had a look, and the more I see of post-prostatectomy cases that are brought to me for reconditioning the less I like touch as opposed to sight in the original operation.

However, Mr. Nitch's experience is so mature that I must refrain from further comment beyond saying I hope that the younger men will not be deterred from trying what I regard as a more reliable method.—I am, etc.,

London, W.1, Feb. 11th. JOHN THOMSON-WALKER.

SIR,—Some years ago I ventured to suggest in your columns (1923, vol. i, p. 259) that Freyer's operation sufficed for the average case of enlarged prostate, and was preferable to the so-called "open" operation; and, further, that, in removal of the gland, "many urologists . . . have become increasingly partial to the two-stage method." For the latter statement I was taken to task by a leader of genito-urinary surgery, who scouted the idea for the simple reason that he "had not heard" of it before.

It was pleasing, therefore, to read in Mr. Cyril Nitch's admirable address on January 26th (p. 139) some confirmation of these views. Quoting the figure of 20 per cent. as roughly the percentage mortality of prostatectomy in London hospitals, Mr. Nitch added "there is no doubt that its gross mortality would be greatly diminished if the two-stage operation were more generally adopted." Few surgeons to-day will be prepared to cavil at his statement; equally few will deny that in the two-stage operation it is undesirable to open up cellular planes and disturb the adhesion of the bladder to the abdominal wall by the free incision and exposure of an "open" operation.

I would submit, then, that prostatectomy after preliminary cystostomy is best and most safely performed bimanually—that is, after the method of Freyer, with the finger in the rectum. Recently objection has been taken to this position of the finger, which undoubtedly facilitates enucleation of the gland. The bogy is sepsis, and a reference typical of many in its warning appears in Ogilvie's *Recent Advances in Surgery*: "the use of a finger in the rectum to guide enucleation has been entirely abandoned owing to risks of sepsis." One must take leave to doubt whether this assertion will attain the importance of a fact.

Of evidence in support of this danger of sepsis there is none, nor is any likely to be forthcoming, for I believe the risk of infection from the rectum is negligible if common-sense precautions are taken. I have always relied upon the protection afforded by a second glove on the hand of which a finger is engaged in the rectum. After enucleation is complete and the finger withdrawn, the outer glove is easily peeled off by a nurse. The protection it affords is adequate for all save the theorist, and the quality of recovery after Freyer's technique I have found to compare favourably with the results of the "open" operation.

By most surgeons, I think, the latter is reserved for cases of "fibrous" prostate, where enucleation is impossible or fraught with danger, and removal under vision obviously indicated. It is by no means a new method. So long ago as 1907 Mr. Rutherford Morison advocated a wide exposure of the bladder base with removal of the prostate under the eye; of recent years the method has been rediscovered and practised both in this country and America.—I am, etc.,

Ashton-under-Lyne, Feb. 9th. GERALD RAWNS.

SIR,—All urologists will be glad to hear of such important first-hand evidence of the value of the treatment of enlarged prostate by diathermy as that experienced by "G. A.," who, in your issue of February 9th (p. 265), writes as both a medical practitioner and a patient. As the doctor himself says, information of this kind is more precise and its interpretation more scientific than that obtainable from a patient without medical knowledge.

In congratulating the patient on the happy result obtained, I would like to add that even in London the line of treatment followed in his case is firmly established as the proper method of dealing with certain cases of prostatic obstruction. On the other hand, it is of equal importance to remember that there is a considerable proportion of cases in which the forage method is unsuitable and is certain to be unsatisfactory. Although the case of "G. A." is not apparently one of these, his letter wrongly gives the impression that the treatment which he received recommended to have in London, but which he received with such benefit in Paris, is not practised by urologists on this side of the Channel. In making it clear that this is not so, I hasten to add that an attempt to deal with the wrong kind of case by coagulation necrosis rather than by prostatectomy may have the most serious consequences for the patient.—I am, etc.,

London, W.1, Feb. 11th. H. P. WINSBURY WHITE.

NOSE-BLOWING AND ACUTE MASTOIDITIS.

SIR,—During the present epidemic of influenza an alarming number of cases of acute mastoid disease is being reported from schools. This complication, with its grave possibilities, is, I feel sure, due to the polite but unnatural habit of the vigorous use of the handkerchief during the catarrhal stage, whereby secretion is forced up the Eustachian tube to the middle ear. The alternative to this procedure requires no description.

As an instance of this mode of spreading infection from the nasopharynx I can recall the history of a small outbreak of acute mastoid disease in a girls' school last year. Investigation definitely traced the outbreak to a nose-blowing competition held as a dormitory amusement.—I am, etc.,

London, W.1, Feb. 10th. BRUCE WILLIAMSON.

SINUSITIS AND ILL HEALTH.

SIR,—One or two articles have recently appeared in your columns relative to sinusitis as a cause of ill health, and they may do much good by bringing this matter into more prominence. In 1925 I published some observations from a series of cases attended at St. Vincent's Hospital, Melbourne, and the rather startling fact was elicited that 25 per cent. of the medical out-patients were suffering from chronic sinusitis—that is, they had a yellow post-nasal discharge accompanied by the usual symptoms of headache, frequent colds, and stuffy nose. It does not matter whether organisms gain entfance from a tonsil, pyorrhoeal pocket, root abscess, or sinus. The organism is the same, and the effects are the same; it is simply another point of entry. These infections are more often than not multiple, so it is useless to clear up the teeth and the throat and to leave the nasal infection.

The idea of a relationship between infections and goitre is gradually gaining ground. In many cases of exophthalmic and toxic goitre, when the tonsils have been removed without improvement, it will be found that the patients have had nasal infection which has been overlooked.—I am, etc.,

Melbourne, Dec. 19th, 1928. SYDNEY PERN.

THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF.

SIR,—In your issue of February 2nd (p. 191) Dr. Harrington Sainsbury tries to establish by inference what I thought was long since proved by experiment—namely, that colloids are practically incompressible. It must be well over a quarter of a century since the late Sir Benjamin Ward Richardson submitted brain and muscle tissue to a pressure of over a ton to the square inch in the hydraulic press of Evans, Lescher, and Webb, Liverpool, and found that they were incompressible, but when he added about 20 per cent. of sodium chloride to the muscle an enormous amount of muscle juice was squeezed out, leaving a tough leathery mass behind. Richardson inferred that salts in the blood, such as urea, etc., were necessary for the excretion of urine. His experiments were published in *The Asclepiad*, but writing from abroad I cannot give a reference to the date. However, I think it highly probable that a presentation copy may be found in the Library of the Royal College of Physicians.

Although blood, like other colloids and water, is incompressible, yet being a liquid it will always move from a higher to a lower pressure level, and it always transmits a pressure equal to that by which it is itself compressed. With the armlet it is difficult or impossible to raise the capillary pressure to that of the arteries, therefore the blood in the compressed artery will move on to the distal capillaries.

In the Valsalva experiment one can shut out the blood from entering the thorax, but here one is only dealing with the venous pressure, and an intrathoracic pressure of a little over 100 mm. of mercury is sufficient to do this. Fortunately this experiment cannot be carried out for any lengthy period. It will require something more than Dr. Sainsbury's inference to convince me that the brachial artery remains full when submitted to a pressure sufficient to obliterate the pulse at the wrist.—I am, etc.,

Cannes, Feb. 5th. JAMES BARR.

PRIMARY CARCINOMA OF THE BREAST TREATED WITH RADIUM.

SIR,—Published statements as to the results obtained in treating carcinoma of the breast with radium have hitherto been very few, and Dr. Roy Ward's article in the *British Medical Journal* of February 9th (p. 242) is therefore to be welcomed. I should like, however, to encourage Dr. Ward to make a very much fuller statement as to the work done at the Radium Institute than he has seen fit to give us.

Mr. Ward refers to the pioneer work which has been carried out; but although several methods of treatment are mentioned, I cannot find any direct statement as to what treatment the patients at the Radium Institute actually received. The value of the article is therefore limited, since it does not contribute to the advancement of technique.

The treatment of recurrent carcinoma of the breast by means of buried radium needles was begun by the Surgical Unit at St. Bartholomew's Hospital in July, 1922, and the first primary carcinoma was treated by this method on August 1st, 1924. So far as I know this method had never been systematically used before.

Again, Dr. Ward's statistical summary, although it gives 164 and 469 as the numbers respectively of primary and recurrent carcinomas treated, gives no information as to the results obtained in these two categories *separately*.

The work on this problem, begun at St. Bartholomew's Hospital nearly seven years ago, tried first the effect of radium on recurrent carcinoma only. The local results were excellent, but the patients' lives were scarcely ever prolonged, owing to the fact that the disease had already been disseminated to other parts of the body. The treatment, on the other hand, of primary carcinoma has proved, during the past four and a half years, to be a very different affair, and as time passes a favourable opinion is being formed. It is possible, therefore, that the results obtained in treating primary carcinoma of the breast at the Radium Institute may also have been good.

Many other points in Dr. Ward's article might also be discussed, but I should like to limit this letter to asking him to publish the facts as to the figures and the technique. —I am, etc.,

London, N.W.1, Feb. 8th. GEOFFREY KEYNES.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

SIR,—Referring to the discussion on this subject which took place at the meeting of the Section of Epidemiology of the Royal Society of Medicine on January 25th,[1] I venture to doubt whether "alastrim" has been proved to be such a stable variant of small-pox as some of the speakers supposed. According to Dr. Rajchman it made its appearance in England in 1919. But the late Dr. J. C. McVail pointed out in the Milroy Lectures for that year that two sorts of small-pox had been prevalent in England since about 1902—a severe form in London, and a milder form in the provinces. The fatality of the mild form was 6 or 7 per cent., of the severe, from 12 to 25 per cent. A very notable fall in the provincial fatality occurred in 1921, when it was only 1.4 per cent. Since that year it has dropped still lower. Is the present-day mild small-pox ("alastrim") a direct descendant of Dr. McVail's mild, provincial form, or is it a later imported variant? And if "alastrim" is a stable variant, was Dr. McVail's mild form also a stable variant? I observe that Dr. Monckton Copeman is reported in the account of the discussion given in the *Journal* to have stated that the "alastrim" he saw in 1903, in and about Cambridge, was of a more severe type than in most of the recent outbreaks. It appears, therefore, that during the past twenty-eight years there have been present in this country, at one time or another, two, if not three, varieties of mild small-pox, besides the classical more or less severe form. It is interesting to note that a similar question of identity of disease has arisen during recent years in the cases of typhus and scarlet fever.

Professor Ledingham is reported (in the *Journal*) to have said he thought "that sufficient consideration had not been given to the possibility that the virulent form of small-pox had been somewhere incident alongside the alastrim, but without definite transitions." I quite agree with his opinion. So far as I am aware the two forms have not, in this country, been prevalent together at the same time in the same place. It would be a crucial test

[1] *British Medical Journal*, February 2nd, p. 205.

for those who believe "alastrim" to be quite a different disease from small-pox, to place cases of each disease together in the same ward of a hospital to observe whether patients suffering from the one became infected by the other.

I note that in No. 2, February 15th, 1928, of the *Monthly Epidemiological Reports*, issued by the League of Nations, it is stated that "small-pox of severe type appeared in June, 1927, in Northern Rhodesia, where ordinarily only the mild Kaffir-pox is met with. During the *first twenty weeks of 1927, 140* cases with only four deaths were reported, giving a case mortality rate of 2.9 per cent.; between the twenty-first and the fiftieth week of that year there were 856 cases and 170 deaths, giving a case mortality rate of about 20 per cent." The questions arise, Was Kaffir-pox (amaas) replaced by severe small-pox, or did the former change into the latter, or did the two run side by side? Perhaps the report of this discussion will be the means of eliciting information on this point. According to the latest returns small-pox has become less frequent and less severe again in Northern Rhodesia. With this history before us we should not assume that the present mild form in England may not at any time become more severe or be replaced by a more dangerous form.—I am, etc.,

Hemingford Abbots, Hunts, Feb. 5th. E. W. GOODALL.

TORSION AND STRANGULATION OF A HYDATID OF MORGAGNI.

SIR,—In the *Journal* of January 26th (p. 144) Mr. D. A. Abernethy records a case of torsion and strangulation of a hydatid of Morgagni in a woman, causing symptoms like a mild appendicitis, and asks if any similar cases have been encountered but not recorded. I have met with one such case, which was more severe in its symptoms than that of Mr. Abernethy, and his communication makes me feel that perhaps I have been remiss in not publishing it before this.

The patient was a young married woman, from five to six months pregnant, who was sent into Kirkcaldy Hospital in a state of collapse. The history was that some eight days previously she tripped going up a stair, and the fall was immediately followed by pain in the left lower abdomen, a feeling of faintness, and vomiting. She was put to bed, and gradually recovered after a day or two. The pain and sickness, however, still persisted, and she had once more to take to her bed, where, despite symptomatic treatment, she steadily became worse, and was ultimately sent to hospital by Dr. Ramsay Wight of Leslie, with a provisional diagnosis of concealed accidental haemorrhage. At no time was there any vaginal bleeding. On admission to hospital she was profoundly blanched, felt very sick and faint, and had a pulse rate of 130 per minute. She was in this condition when I saw her an hour later, but the pulse rate had gone up to 140. She was a thin woman and the abdominal wall was not rigid. Slight pain and tenderness were complained of over the left lower quadrant of the abdomen, but otherwise abdominal and pelvic examination revealed nothing abnormal. The pregnancy appeared to be a normal intrauterine one of five and a half months; the shape and consistence of the uterus and the absence of any tenderness over it did not substantiate the diagnosis of accidental haemorrhage, and, moreover, the foetal parts were palpable with an unusual degree of ease. I was, frankly, quite unable to form any positive diagnosis. The patient's condition suggested internal haemorrhage, but there were no physical signs of any collection of blood. I suggested, as a very tentative diagnosis, the possibility that she had perhaps ruptured her uterus, and as the patient had been gradually becoming worse I decided to explore the abdomen. While the necessary preparations were being made, Mr. F. E. Jardine, consulting surgeon to the hospital, happened to arrive, and I asked him to examine the patient, but did not tell him of my "diagnosis." After careful examination Mr. Jardine told me that he could suggest no positive diagnosis, but he thought that possibly she might have ruptured her uterus! We opened the abdomen together and found a normal pregnancy, no sign of any ruptured viscus in any part of the abdomen, nor any bleeding. But below the extremity of the left Fallopian tube there was a hydatid of Morgagni of the size and of the colour of a black-crimson cherry, hanging by a thin and very much twisted stalk. I removed this, after tying a piece of fine catgut round the base of the pedicle, and we closed the abdomen. The patient made a steady and uninterrupted recovery, the pregnancy continued without interruption, and Dr. Ramsay Wight informs me that she was delivered of a healthy child at full time, the placenta showing no sign of any previous disease or separation.

I cannot offer any adequate explanation of the severity of the symptoms, except that possibly the torsion of the hydatid served to set up something akin to a "reflex" hyperemesis gravidarum. But why the patient should have been so alarmingly collapsed and pale I do not know, for the "hyperemesis," if such one may call it, was not of itself sufficient explanation.—I am, etc.,

Edinburgh, Jan. 31st. R. W. JOHNSTONE.

SIR,—Mr. Abernethy will find the record of a case of torsion and strangulation of a hydatid of Morgagni reported by Waters in the *Journal of the American Medical Association*, 1919, vol. 72, p. 1072.

A further case is recorded by Russell Andrews in the *Proceedings* of the Royal Society of Medicine (Obstetric and Gynaecological Section), 1912, vol. 22, p. 220; in this case the patient was pregnant.

In 1923 I presented to the North of England Obstetric and Gynaecological Society a case of strangulation of a small fimbrial cyst measuring a quarter of an inch across. The case is briefly reported in the proceedings of the Society in the *Journal of Obstetrics and Gynaecology of the British Empire*, 1923, vol. 30, p. 313.

My case is not absolutely comparable to the above as there was no visible pedicle and the strangulation lay at the upper margin of the tube. It is of interest, however, that such a small area of strangulation should have produced subacute symptoms of vomiting and fainting. The removal of the small area was followed by an immediately good result. The condition of strangulation was confirmed by microscopical examination.—I am, etc.,

Liverpool, Jan. 31st. H. LEITH MURRAY.

SIR,—Since the publication of my account of a case of strangulated hydatid of Morgagni in the female, in your issue of January 26th (p. 144), I have learned that this lesion has been described previously by Dr. Russell Andrews who published an account of it in the *Clinical Journal* (September 10th, 1913, p. 362).—I am, etc.,

Oxford, Feb. 4th. D. A. ABERNETHY.

PROGNOSIS IN ECLAMPSIA AND ALBUMINURIA OF PREGNANCY.

SIR,—The important paper by Dr. James Young, published on January 19th (p. 91), with conclusions which conflict with ideas which were largely accepted by workers in this field until now, leads me to raise some points which may help in these problems.

1. What positive evidence as yet is there available to us that "kidneys were previously healthy"—to quote Professor Young's exact words in the second argument brought forward in favour of the thesis that the kidney defect is not, at any rate, one of the primary factors. Unfortunately it is most unusual for renal adequacy or inadequacy to be assayed, at any rate on modern lines, before pregnancy, and especially the first pregnancy, even Gibberd[1] in his report was guarded, and classed his cases as "presumably" healthy beforehand.

2. The evidence cited as having been collected by Professor Young by Dr. Jessie Sym is based on the cardiovascular changes, renal concentration tests, and blood pressure indices. Valuable as these are, one would urge caution in considering them conclusive evidence as to renal efficiency or not. Gibberd goes so far as to say that it is in pregnancy itself that we have the most delicate tests of renal efficiency, and suggests that biochemical tests are of comparatively small value. I am not willing to go so far as that yet, but the point should not be overlooked in these obscure and difficult problems; turning to the [illegible] report by Cruickshank and others,[2] we find they [illegible] extreme difficulty in deciding whether an albuminuria of pregnancy is a "simple toxic" or a "nephritic" case, though their biochemical examinations were most extensive.

3. There is in my experience a difference between the course of the subsequent pregnancies which distinguishes the frank renal cases from the purely toxic ones. In the latter the tendency is for there to be a more [illegible] gestation—six to eight months commonly before [illegible] trouble—while in the former the pregnancy is [illegible]

[1] *Proc. Roy. Soc. Med.*, March, 1928, vol. xxi, p. 851.
[2] *Toxaemias of Pregnancy.* Medical Research Council, Special Series, No. 117.

at an increasingly early period as the patient goes downhill, and the kidney fails.

4. Lastly, and lest my criticisms should be all destructive and not helpful, I would point out that the possibility of a (normal?) full-time pregnancy with living child, in cases of *known* extensive renal disease, has been often observed, showing, perhaps, that the renal disease is not necessarily the whole factor in these cases.

I have ventured to encroach on your space so far, as I have just finished collating and analysing a series of over a hundred cases, not yet published, some of which have been watched during a long period, some over thirty years, and part of the results do not appear to support Dr. Young's deductions. I am sure all workers in this difficult field will welcome his paper, and that it will be helpful in many ways, one of which will be the criticisms that it may evoke.—I am, etc.,

Norwich, Feb. 5th. ARTHUR CROOK.

ASTHMA.

SIR,—On first perusing the letter of the Asthma Research Council their statements appeared to be merely platitudes; but on reading the assertions made by some of your correspondents, I am inclined to agree that these apparent axioms are in still further need of emphasis.

I have every reason to know that the claims about curing asthma made by certain chemical pathologists are disappointing. There is a manifest fallacy in the theory that foreign proteins which give a reaction when injected hypodermically, or scratched into the skin, will therefore cause disturbances when swallowed, even if they do so sometimes. I venture to suggest that if some of those who are in the habit of eating beef or mutton were to inject themselves hypodermically with 10 c.cm. of beef or mutton serum, they would have some reason to remember the occasion.

Though I practise the nasal method of treatment myself, I am the first to realize that exaggerated claims have been made for it, based upon statistics containing large numbers of untraced cases. Mr. Herbert Tilley has pointed out in his textbook how often these relapse months or years after an apparent cure.

My own experience is that only those patients who have no gross lesions, and who give a positive tear-reflex test (*Journal*, December 1st, 1928, p. 985) are likely to do really well by nasal treatment. Such patients should, in my opinion, be treated in a very conservative way, efforts being devoted to rendering the hypersensitive mucous membrane insensitive by means of the galvano-cautery or other caustics. This is my experience after reviewing a series of cases from four to six years after treatment. The only operation which has not disappointed me has been removal of tonsils.

But whatever the experience of individuals may be, there can be little doubt that some co-ordination of knowledge and sifting of evidence is essential.—I am, etc.,

London, W.1, Feb. 9th. H. MORTIMER WHARRY.

THE DICK TEST IN SCARLET FEVER.

SIR,—In reply to Dr. Balmain, who asked, on January 26th (p. 175), what was the size of the Dick reaction which I considered positive, I never regarded anything less than 5 centimetres as positive. The nurse to whom he referred was found to be Dick-negative at two examinations, one being two months before and the other three weeks before her attack of scarlet fever.

Until I had read the article by Dr. Burton and Dr. Balmain in the *Lancet* of May 26th, 1928, I was surprised that Dr. Balmain disagreed with me when I asserted in my article that it was impossible, in the present state of our knowledge, to say that a positive Dick test in a patient who had had scarlet fever indicated a failure to develop immunity to this infection. In that article Drs. Balmain and Burton stated as follows: "We would suggest, however, that the Dick-positive reactors in convalescent scarlet fever cases are persons who have failed to develop immunity." I would point out to Dr. Balmain that among the high proportion of Dick-positive reactors in convalescent scarlet fever patients in my series not one developed scarlet fever, and they were all treated in an acute ward. The late Dr. Zingher, in the admirable article referred to by Dr. Balmain and myself, said "Positive Dick reactors are susceptible to scarlet fever as far as not having antitoxin is concerned," and again, "Positive Dick reactors, however, need not necessarily develop scarlet fever when exposed to the disease." I was very pleased to notice that Drs. Balmain and Burton referred to their eighteen cases as true relapses, because it has always seemed to me to be of the greatest importance in investigating any case of a relapse or a second attack of scarlet fever to make certain that the first attack had been genuine.—I am, etc.,

Doune, Feb. 4th. WILLIAM BROWN, M.D.

"DEBILITY" IN CHILDREN AND CYCLICAL VOMITING.

SIR,—Dr. Osman writes an important and interesting article in your issue of January 26th (p. 150) on debility and cyclical vomiting. Dealing with the latter subject only, I am unable to accept unreservedly his sugar deficiency theory, as it does not seem to cover all the facts.

It is not uncommon to see a child who has exhibited all the symptoms of cyclical vomiting quite cured after adequate treatment with santonin for round-worm.

Dr. Osman draws attention to the similarity between cyclical vomiting and recurring appendicitis. Differing from him, I consider that frequently the latter is the starting point of all the symptoms. Time and time again I have seen the attacks finally stopped by removal of an offending appendix; and it does not convince me when I am told that extra sugar in the diet might have produced an equally favourable result.

Having seen, as a practitioner, many cases of cyclical vomiting, the impression I have formed is that it is not an absolute clinical entity, but a symptom group resulting sometimes from one cause and sometimes from another. If Dr. Osman's theory turns out to be even partly correct, we must thank him for providing us with a potent weapon against the malady.

In the excellent description of signs and symptoms given in the article two rather constant signs are missing—namely, a dusky malar flush and the so-called acetone odour in the breath.—I am, etc.,

Lerwick, Feb. 4th. JAMES CAMPBELL, M.B., Ch.B.

SIR,—It would be almost impossible to reply in detail to every one of the many interesting points raised by Mr. R. Chalmers and Dr. J. Thomson Shirlaw on February 9th (p. 269) in their friendly criticisms of my article on the above subject. To do so would occupy a great deal of space, and most of the points have been covered in a further paper on the subject which will appear in due course.

I would like to make it clear, however, that the statements in my article were not based simply on the finding of acetone bodies in the urine of these children, but on a very comprehensive clinical and biochemical study of a large group of cases, carried out over a considerable period. The observations made included estimations of the blood bicarbonate, chloride, inorganic phosphates, calcium, sugar, and total acetone bodies, together with careful chemical investigations of the urines of these cases at the same time. In a number of instances also bilirubin estimations on the blood, fractional test meals, alimentary x-ray examinations, and glucose and levulose tolerance tests were also employed. Further, corresponding observations have been made on a series of "debilitated" adults; the results of these observations will be published in the paper referred to.

I should like to take this opportunity of discussing in a little more detail the position with regard to "acidosis" in relation to "debility." For this purpose the term "acidosis" may be defined as a reduction of the plasma bicarbonate. Such reduction may, or may not, be due to, or associated with, an excess of ketone bodies in the blood; that is to say, a condition of acidosis may be present, and frequently is, without acetonaemia, etc. As a matter of

fact, it has long been known that ketosis may occur in the presence of an alkalosis. Most of the "debilitated" children referred to in my article were suffering from a mild acidosis. Only a small proportion of them had at the same time ketosis, so far as could be ascertained by the tests used. Of the "debilitated" adults referred to in this letter, hardly any had a ketosis associated with the acidosis. Further, in those children in whom both acidosis and ketosis were present the latter was insufficient quantitatively to account entirely for the former.

I cannot therefore agree with the findings of Gamble, Tisdall, and Ross concerning this point. No doubt the ketosis, when present, is due to incomplete combustion of fats, as Dr. Shirlaw remarks, but the acidosis without ketosis is still unexplained. Why it is that the giving of sugar should benefit these non-ketotic cases, as it undoubtedly does, is also at present a mystery. Ketosis is, of course, more commonly met with in children than in adults, because, in the former, owing to their comparatively poorly developed cerebral inhibition, with consequent lack of emotional control, greater and more frequent calls are made on the glycogen stores of the liver. It is for this reason, too, I think, that the symptoms described in my article under the heading of "debility" are more marked in nervous children, but they are certainly not confined to them. Such a conception would explain the comparative failure of sugar in the treatment of the "debility" of adults. The one biochemical finding which is present in all these children is a lowered plasma bicarbonate, though the diminution may only be slight. I would therefore suggest that, until our knowledge of the subject is more complete, the term "the acid child" would be correct and convenient, and would best describe the patient. I agree with Mr. Chalmers that one occasionally comes across a child, and even a whole family, who exhibits an apparently inherited dislike for sugar, but this is exceptional.

With regard to the importance of atmospheric conditions in determining the onset of attacks of cyclical vomiting, I also agree with Mr. Chalmers. During the past few years I have certainly seen several cases of asthma in children in whom the attacks were entirely prevented by giving sugar, and others in whom the frequency and severity of attacks were diminished by the same means. On the evidence available one can only conclude that this was due to the associated improvement in the general health of the child.

With regard to Professor Vining's investigation of the pre-rheumatic health defect in children, I believe that his work constitutes the most important step yet made in the study of the rheumatic child, though I cannot quite agree with his views on the nature of the particular dietetic error concerned.

Finally, I agree with Mr. Chalmers's implication that simply giving extra sugar to children is not the beginning and the end of the whole problem. That such a procedure is very frequently successful in restoring to health many children afflicted with various minor disorders there can be no doubt. It is equally certain that the best results will only be obtained by the prescription of a correctly balanced diet, and this can only be achieved as a result of carefully conducted experiments on children living under varying conditions.—I am, etc.,

Queen Mary's Hospital, E., Feb. 11th. ARTHUR A. OSMAN.

TREATMENT OF EMPYEMA.

SIR,—I hope the able remarks of Dr. F. G. Thomson about empyema in the *Journal* of January 19th (p. 89) have received the attention they deserved from your readers. He shows that under the usual method of treatment the mortality in this disease is heavy, and the result too often crippling in those who survive.

My experience, covering a period of forty-three years in a fairly busy general practice at Rhyl, prompts me to write to you. In that time I have treated many cases of empyema, both in adults and children, the youngest of the latter being 6 months old, and of the total number of cases I cannot recall a death or even permanent impairment, except, perhaps, in one or two tuberculous cases.

The following were the methods I generally adopted. On ascertaining the presence of pus, the affected side was completely aspirated, and later, as pus re-accumulated, an incision was made, with or without rib resection, and a tube introduced of efficient size for drainage. The cavity was irrigated daily with a solution of iodine. Turpentine was employed in nearly all such cases, as it was often markedly beneficial. Administered as follows it is not so unpalatable as generally imagined:

R Ol. terebinth. pur.	3ij-3iij
Pulv. tragacanth. co.	3iss
Sp. amm. arom.	3iij
Aq. chlorof.	ad 3viij

Misce. Cap. 3j 4tis horis.

Aspiration empties the chest without the introduction of air, thus giving the best chance of expanding the compressed lung, of lessening the abscess cavity, and of speedily relieving embarrassed breathing. The patient has a welcome respite, and when the time comes for the next procedure of opening the chest and introduction of the tube, he is exposed to less danger. The presence of air in the cavity does not matter so much then. If there is evidence that the lung has not expanded enough it is better to aspirate again than to open the chest, for a closed pleural cavity offers the only chance of recovery to a compressed lung.—I am, etc.,

Prestatyn, Jan. 28th. W. THOMAS.

ERYTHEMA NODOSUM.

SIR,—Dr. G. F. Walker, in his interesting l
(February 9th, p. 266) outlining a summary of the st
of this disease, says, "Priority for the notion t
erythema nodosum may be the rash of an acute spec
infectious disease belongs to Dr. Harrison, who was pre
dent of the Dermatological Society in 1900." It must
remembered, however, that just thirty years prior to D.
Harrison's presidential address, Trousseau, in his clinica
lecture on this disease (vol. ii, New Sydenham Society's
Transactions, London), said, "Erythema nodosum is a
specific and separate disease, which manifests itself locally
by characters so precise as not to admit of being mis-
taken." I agree with Dr. Walker that clinically it is far
more important to settle the relationship between erythema
nodosum and tuberculosis than to argue the vexed
question as to its specific nature.—I am, etc.,

Clifton, Bristol, Feb. 9th. J. ODERY SYMES.

THE ADRENAL GLAND.

SIR,—The recently published work of Dr. Cramer on le
regulation and the thyroid and adrenal apparatus contai
a description of the resting and active medulla of the supra-
renal gland. He finds that by fixing the gland in th
vapour of osmic acid the granules of adrenaline are rendered
visible. Adrenaline readily reduces osmic acid to the blac
lower oxides, appearing as fine black granules. Any fluid
fixative will dissolve the granules of adrenaline before it
can fix them. He says:

"In the active gland the adrenaline granules in the c
adjacent to blood vessels can often be seen being poured directly
into the blood vessel. The capillary blood spaces, and especially
the big central vein, are filled with these black granules in the
midst of which the red blood corpuscles are lying. Sometimes
the charge is so violent that the endothelial lining separates from
lumen of the small veins from the cells bordering them is free
off and small parts of the cytoplasm are swept into the blood
stream, where they can be seen. Occasionally the vacuoles formed
in a group of cells which constitute an alveolus, coalesce in the
centre so as to form a lumen into which the adrenaline granules
are secreted."

It is a curious fact that in the *British Medical Jo*
of July 4th, 1896 (p. 10), I published an account of the
behaviour of the active body of the medulla of the supra-
renal gland, which corresponds exactly to the above. The
article is illustrated by three photographs, which, in the
Selected Researches in Pathology (1901), came out very
clearly on special paper. The words are:

"After a long and varied series of investigations made on man, horses, oxen, sheep, dogs, rabbits, etc., I arrived at certain definite conclusions respecting the mode of secretion by the epithelial gland cells, the transmission of this secretion to the blood, and certain other interchanges which take place between the secreting cells and the blood. . . . When about to become active the cells of the columns become highly elongated, and their nuclei recede from the blood vessels to the very furthest point, until in this way the nuclei of any two opposite rows meet, forming thus a double row of nuclei. On either side the protoplasm of the columnar cells will be clearly seen stretching to the blood vessels (Fig. 1). . . . The protoplasm of the cells thereupon assumes a finely, but markedly granular character, and the granules become so disposed as to form frequently longitudinal streaks perpendicular to the wall of the blood channel; simultaneously the ends of the cells become flattened against the delicate membrana propria, through which the secretion *streams directly into the blood*. (Fig. 1: Note that in this particular instance the contents of the blood vessel are in the form of a homogeneous coagulum.) . . . It sometimes happens that the secretion breaks down the membrana propria altogether, and the blood and cells come into direct contact. (Fig. 2: The blood is normal in this case.) . . . In like manner we find that sometimes a local secretion occurs among groups of cells, undischarged into the blood, and then we have a mass of secretion lying amongst, and to some extent displacing, the cells (Fig. 3)." [This mass is distinguished from the coagulated contents of vessels by its staining reactions, etc.]

Dr. Cramer's observations were made on mice and rats, but I used large animals, such as the horse and sheep. The resting medulla with its large nuclei described by him, and the small nuclei of the active cells, are seen also in my figures. In my book it is stated that "the foregoing observations were made antecedent to the experimental work which in the hands of Oliver and Schafer and Abclous and Langlois has been fraught with interest and importance." The conclusion is come to that this substance is a powerful reducing agent, and that the toxic body or bodies of Addison's disease are normally destroyed in the gland itself.—I am, etc.,

London, W.1, Feb. 5th. A. GUNN AULD.

CEREBRAL ANGIOSPASM.

SIR,—The case described below may be compared with that of Dr. A. S. Gubb (February 9th, p. 247). More than forty years ago I was asked by a medical friend to see his wife, aged about 75, who had been struck with right hemiplegia. The following features of the case still remain in my memory. The patient rose in the morning feeling somewhat ill, but dressed herself until it came to doing her hair, when she found herself unable to use her right hand. She returned to bed, and within a few minutes the paralysis extended to the whole right side. She was drowsy but able to speak. Her breath was foul, smelling of bile. A little later she vomited a quantity of matter containing bile, and from that time got better, recovering the use of the right side before the end of the day. She lived for about five years afterwards, had no return of paralysis, and died of carcinoma of the liver.—I am, etc.,

Cambridge, Feb. 11th. F. J. ALLEN.

ACTINOTHERAPY AND DEAFNESS.

SIR,—The probable explanation of the case quoted by Dr. T. C. Hunter in his letter (January 19th, p. 133) is that the nurse in question was suffering from functional, not organic, deafness. This was possibly associated with lowered vitality, chiefly indicated in her case by defect in this special sense. Her removal to work under conditions which exposed her to the action of ultra-violet rays improved her general condition, leading to an increase of activity in the sense of hearing. This by no means implies the recognition of ultra-violet rays as a treatment for established organic deafness. Such cases as that reported by Dr. Hunter are occasionally met with, and require careful diagnosis; they have probably some relationship to the better recognized "hysterical" deafness. Chronic progressive deafness should not, however, in my opinion, be considered as a "degenerative disease" in the majority of cases.—I am, etc.,

Bath, Feb. 4th. H. NORMAN BARNETT.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Local Government (Scotland) Bill.

THE committee stage of the Local Government (Scotland) Bill began in the House of Commons on February 4th. Considerable discussion took place on Clause 1, which provides for the transfer of the functions of parish councils and district boards of control to county councils and town councils of large burghs. Sir A. SINCLAIR moved the deletion of the provision relating to the parish councils. Sir J. GILMOUR replied that the new central authorities to be set up would be the elected representatives of the people, charged with certain duties, but it was clearly indicated that these bodies should submit definite schemes showing in detail how they would carry out their duties. In the case of the Poor Law it was obvious that there must be within those schemes such measure of arrangement as would ensure that immediate relief was given to the necessitous people within the district. The real essence of the bill was that there should be a large amount of elasticity in order that the peculiar problems of particular areas might be dealt with. The Government were abolishing out-of-date machinery and obtaining in its place the best machinery possible. In the course of further discussion, Dr. ELLIOT explained that it would be possible to treat the sick poor under Acts other than the Poor Law. The amendment was defeated by 193 votes to 93.

Sir J. GILMOUR, dealing with the duties to be transferred from parish councils to district councils, said that, with certain exceptions, the duties were the same as the parish councils were performing to-day. The chief exception was that of the Poor Law, but in the matter of dealing with outdoor relief the central body might under their scheme delegate some part of the work to the district councils. The amendments, moved by Sir J. Gilmour, to carry out a previous undertaking, were carried, and the clause was added to the bill.

On Clause 2, which deals with the transfer of certain other functions to the county councils, Dr. SHIELS moved the omission of paragraph (*b*), which transfers the functions of town councils of small burghs within the county as local authorities for the purposes of the statutory provisions set out in Part I of the first schedule. Dr. Shiels said that the proposal did not seem to have any justification, and had no relation to the de-rating proposals. The county councils were upstarts, whereas the small burghs had, for hundreds of years, been places of efficient government. Sir J. GILMOUR replied that different commissions and inquiries had repeatedly urged the setting up of larger areas. It was not the case that the county councils were inefficient. The small burghs, under the Government's scheme, play a very large and important part in the policy and administration with which the new larger authorities would be entrusted. The amendment was rejected, and the clause added to the bill.

On February 5th the whole of the time available for debate was given up to a discussion of an amendment by Sir R. HAMILTON to Clause 3 to omit the subsection providing for the transfer of the functions of the education authorities. Dr. ELLIOT, replying to the debate, said that the education authority of Scotland had been deemed on more than one occasion to be ripe for reform. The method which the Government were bringing forward was not suggested by anyone but by the great civil servants who had to advise the Government. It was deeply worth while to make this great change for the sake of the benefits which they expected to derive from it. At this moment a recasting of local government was taking place in Scotland, and they expected an extension and enlargement of the powers of the central bodies—the county councils and the town councils—to take place which would raise them to a position of prestige and dignity which they had never enjoyed before. By a new grant their hands were being freed to a very large extent from many of the niggling controls which it was necessary to place on them when the system of the percentage grant was introduced. Furthermore, the Government were, in the health clauses, making it possible to alter the health system of Scotland along the lines which the health reformers had been demanding for many years past. When all these great changes were taking place it would be folly, and criminal, to leave out of account the 800,000 school children who were the flower of Scotland, and who were the people on whom they relied for the whole national life of Scotland in the years to come. The time had gone past when it was possible to treat the mind of the child apart from the body of the child. To do that there must be the close and intimate connexion of the great new authority which was responsible, not *ad hoc* for health but *ad omnia*, as health was one of the major functions. If health was not too important a subject to put into the hands of this great new authority, then education was not too important either. If they could entrust this new authority with the terrible and powerful responsibility of the tender years of child life of Scotland from 1 to 5, and with the life of the adults of Scotland from school age to death, and the bodies of Scotsmen and Scotswomen, it would be going back on all that they were bringing forward, and

on the whole theory of health as one of the most important of modern functions, to say that the body was a secondary thing, and that an *ad omnia* authority could take charge of the bodies of the people of Scotland, but that there was something so sacred in this question of book-learning that it had got to be removed entirely from the ambit of that authority and to be put under different control. The Government's theory and conviction was that the body was as sacred as the mind, and if they could make a strong, fit, and burly generation of young Scots then they would have done something to which the making of the mind of the Scotsman and Scotswoman was not a secondary thing. That was their contention, and the contention of the great medical school. Hon. members could call it, if they would, a materialistic ideal, but they did not regard it as such. They said that the formation of the fit citizen could not be carried out unless the supervision of the citizen all the way through was entrusted continuously to one responsible authority.

The amendment was defeated and the clause agreed to.

Clauses 4, 5, and 6 were agreed to under the guillotine, also Clause 7, which provides for the transfer of officers and superannuation funds.

On February 7th Major ELLIOT moved an amendment providing that administrative schemes might be made for the treatment of persons suffering from disease, infectious or otherwise, lunatics and persons mentally deficient, expectant or nursing mothers, young children or blind persons, otherwise than by the Poor Law Acts. He said this had to be taken in conjunction with a new clause, to be moved later, dealing with the wide extension of hospital facilities.

Several Labour members complained that the amendment would leave certain sick persons to be treated under the stigma of the Poor Law.

Sir JOHN GILMOUR said the amendment made a definite change and advance. That it should be mandatory was not practicable. It proposed that the authorities should produce schemes by which sick persons who were not under the Poor Law but in poor circumstances could be treated. The authorities could then recover from them such amounts as were thought desirable.

The amendment was approved by 197 to 107.

Radium.

Mr. CHAMBERLAIN, speaking on February 7th, said he had no funds at his disposal for the purchase of radium, and he did not know whether work was continuing at the mine in Cornwall where radium deposits had been found. The Government would consider the whole question of the purchase of radium when a report had been received from the subcommittee of the Committee of Civil Research, which was looking into the subject. He expected this report within a year.

Mr. A. M. SAMUEL, on February 11th, informed Mr. Benn that "radium compounds" were included in the list of chemicals liable to a duty of 33⅓ per cent. ad valorem issued by the Board of Trade under Part I of the Safeguarding of Industries Act, 1921. These compounds were, however, exempted from duty until June 30th next by a Treasury Order made under the Finance Act of 1926. Radium was not dealt with commercially except in the form of a compound.

On February 11th Sir KINGSLEY WOOD, replying to Mr. R. Morrison, said that the Minister of Health had approved arrangements under which the Edmonton Board of Guardians would obtain a supply of radium for the treatment of forms of cancer at the infirmary of the guardians which was known as the North Middlesex Hospital. One of the terms of the arrangement was that if the radium was not in use for persons chargeable to the guardians it should be used for similar cases from other unions in the adjacent parts of Middlesex. There had been and would be no avoidable delay on the part of the Minister of Health in bringing the arrangements into operation.

Protection of Animals (Amendment) Bill.

Lord BANBURY moved the third reading of the Protection of Animals (Amendment) Bill in the House of Lords on February 7th. The purpose of this bill was to prevent the issue of dog licences to persons convicted of cruelty to dogs. Lord SALISBURY thought the proposal was cumbrous and very ineffective. He could not agree to an amendment inserted at a previous stage to provide that any person applying for a dog licence must sign a declaration that the application was not made directly or indirectly for anyone whose licence had been revoked or suspended. After further debate the bill was rejected by 24 to 18.

Deaths from Cancer in Scotland.—Sir J. GILMOUR, on February 12th, told Mr. R. MORRISON that last year 11 males and 16 females under 15 years of age, and 3,005 males and 3,870 females over 15, died in Scotland from cancer. This made a total of 6,902 deaths of persons of all ages.

Assessment of Voluntary Hospitals.—Mr. CHAMBERLAIN told Sir Arthur Holbrook, on January 31st, that he had received some representations about the increases recently made in the assessments of voluntary hospitals. The exemption of hospitals from rating could not be effected without legislation, and he thought that it could not be considered apart from the similar claims made on behalf of other charitable and public institutions.

Pensions Appeals.—Mr. CHAMBERLAIN told Mr. Tasker, on January 30th, that during the year ended September 30th, 1923, 174 appeals were received by the Ministry of Health from persons whose claims to pensions had been refused by local pensions committees on the ground that the claimants did not appear to fulfil the statutory condition of blindness. Of these claims, 111 were decided in favour of the claimants.

Grants for Maternity and Child Welfare Schemes.—On February 7th Mr. CHAMBERLAIN said that even if schemes for buildings connected with maternity and child welfare work had been approved by the Ministry for a 50 per cent. grant these grants would be wholly discontinued after March 31st, 1930, and absorbed in the new grants to be given under the Local Government Bill.

Discharge of Criminal Lunatics.—Asked how he was guided in deciding on the release or detention of a criminal lunatic, Sir W. JOYNSON-HICKS said that so far as medical considerations were concerned he was guided mainly by the skilled medical authorities at Broadmoor Criminal Lunatic Asylum, or, if the patient were in a local mental hospital, by the views of the superintendent and of his own medical advisers. All criminal lunatics were under medical observation, and reports on each were made to the Home Secretary by the superintendents of the asylums. Discharge did not depend entirely upon any single definite factor, such as entire recovery or complete cure.

Nervous Disorders of Telephonists.—On February 12th Sir W. MITCHELL-THOMSON told Sir R. Thomas that, in 1926, out of 79,712 days of sick leave taken by London telephonists, 4,913 days were attributed to neurasthenia, nervous debility, nervous exhaustion, nervous shock, and neurosis; 385 days to neuritis; and 1,592 days to neuralgia. The total number of telephonists employed was 7,051; but there was no record of the number absent on account of these disorders.

Protection against Attack by Air.—Mr. BALDWIN informed Mr. R. Morrison, on February 12th, that the problem of the protection of the civil population against air attack was being closely studied in all its aspects, including protection from chemical gas. The need for the preliminary training of personnel and for the preparation of full and precise instructions to all concerned was not overlooked.

Sanitary Conditions in Hop-growing Areas.—Mr. CHAMBERLAIN, replying to Sir R. Thomas, on February 12th, said that he was aware that in some areas in Kent the sanitary conditions were during the last hopping season unsatisfactory. He was not, however, aware of any evidence suggesting that an outbreak of infectious disease was attributable to those conditions, and, in fact, the number of cases of notifiable infectious disease reported from the districts in which imported pickers were employed was not abnormal.

Hygienic Conditions of Crew Spaces on British Ships.—Dr. VERNON DAVIES asked the President of the Board of Trade, on February 6th, whether the joint committee recently set up by him and by the Minister of Health would inquire into the hygienic of crew spaces on board ship. Mr. HERBERT WILLIAMS, answering for the President, said a series of special reports on the subject had been placed before the Joint Advisory Committee set up by the Ministry of Health and the Board of Trade. Dr. DAVIES asked if representations had been received from the Society of Medical Officers of Health, the Royal Sanitary Institute, and the Association of Port Sanitary Authorities, stating that the conditions under which British seamen were housed on British ships were, from a hygienic standpoint, unsatisfactory and inferior to those on ships of other nationalities. Mr. HERBERT WILLIAMS said representations had been received from one body, and would be considered in any amendment of the crew space regulations which were now under review. Conditions on some British ships were satisfactory, but it was misleading to suggest that crew spaces on British ships generally were unsatisfactory from the hygienic standpoint and inferior to those on foreign ships. Since 1913 many changes made in the Board of Trade instructions had been in the direction of a higher standard.

Notes in Brief.

The Secretary for Dominion Affairs has no information as to the existence of promising deposits of uranium ores in Australia.

The published information does not permit the Ministry of Health to compare the rates of mortality from puerperal sepsis in Germany, Sweden, and France with those in England and Wales.

Sir J. Gilmour is prepared to undertake that the welfare of blind persons will not be prejudiced by the provisions of the Scottish Local Government Bill.

Mr. AMERY states that there are three European hospitals in Kenya with 46 beds, and twenty-nine non-European hospitals with 153 beds. In 1927 the two classes treated 27,605 in-patients and 176,281 out-patients.

On February 7th Commander KENWORTHY presented a petition signed by 9,829 persons, praying the House of Commons to prohibit vivisection.

Mr. Chamberlain announced, on February 7th, that he hoped to lay on the table at an early date the report of a Ministry of Health medical officer who recently visited the distressed areas in South Wales.

[An account of the debate on the report stage of the Local Government Bill will be published next week.]

Obituary.

SIR ALEXANDER OGSTON, K.C.V.O.,

M.D., C.M., LL.D.,

Extra Surgeon to the King in Scotland; Emeritus Professor of Surgery, University of Aberdeen; Consulting Surgeon to the Aberdeen Royal Infirmary.

WE had to record last week, with much regret, the death, at the age of 84, of Sir Alexander Ogston, Past President of the British Medical Association, which took place on February 1st at his home in Aberdeen.

Alexander Ogston, eldest son of Francis Ogston, professor of medical jurisprudence in the University of Aberdeen, was born in April, 1844. He received his medical training first at Aberdeen, then later abroad, at Prague, Vienna, Berlin, and Paris, graduating M.B., C.M.Aberd. (with honours) in 1865, and proceeding M.D. a year later. After his study tour of the leading medical schools of Europe Alexander Ogston returned to Aberdeen, where he soon built up a large practice, at first general, but later, with his growing reputation as a surgeon and skilful operator, purely consulting. In 1865 he was appointed assistant to his father, a position he held till 1873. From 1868 till 1872 he was joint medical officer of health for Aberdeen, and in 1872 was put in charge of the small-pox isolation hospital that had been specially set up in that city. His connexion with the Royal Infirmary began in 1868, when he was appointed ophthalmic surgeon; two years later he became junior surgeon, being appointed acting surgeon in 1874 and senior surgeon in 1880. This post he held till his resignation in 1898, when he became consulting surgeon. While holding his various posts at the Royal Infirmary he was actively associated with the University of Aberdeen. In 1869 he was appointed university lecturer in practical ophthalmoscopy, and in 1873 he became examiner in medicine, a position he held till 1876. On the retirement of Professor William Pirrie in 1882 he became regius professor of surgery, which office he retained with distinction for twenty-seven years. As a teacher his work was inspired by high ideals, and under his supervision the department of surgery grew in strength and efficiency.

SIR ALEXANDER OGSTON.

Alexander Ogston, himself educated before the days of antisepsis, at a time when hospital wards teemed with erysipelas and septicaemia, was an early convert to Listerian methods, his own research into the cause of acute suppuration resulting in the discovery of the *Staphylococcus pyogenes aureus*. Early in his career he devoted himself to bone surgery, the "Ogston operation" for genu valgum being extensively practised until it was displaced by Macewen's method. The very name "staphylococcus" was originated by him in 1883, when he was struck by the resemblance between clumps of cocci and bunches of grapes.

But it was in military surgery that his deepest interest seemed to lie; "he was," in the words of Sir James Porter, "the first pioneer in dealing with the medical conditions prevailing in the Army and Navy in modern times." Though it was the Franco-Prussian war of 1870–71 which specially directed his attention to this branch of surgery, it was not until the Egyptian war of 1884–85 that he had his great opportunity of mastering its practice. He set out for Egypt in 1885, and, after some service on the hospital ship *Ganges*, joined the First Bearer Company, and soon found himself in the thick of actual fighting. At Hasheen and Suakin in particular he was able to do excellent work among the wounded; for his services and personal bravery he was awarded the Egyptian war medal and the Khedive's bronze star, and at home received the thanks of the British National Society for Aid to the Sick and Wounded in War. His next experience of active service was in South Africa in 1899–1900, and on his return he was appointed a member of a committee of medical experts set up by the Government to consider a scheme for the future organization of the Army Medical Corps, and some of the suggestions he then made have since been carried out. Though at the outbreak of the great European war (1914–18) he was 70 years of age, Sir Alexander Ogston acted as operating surgeon to the Southall Auxiliary Military Hospital during the winter of 1914–15, proceeding subsequently to Belgrade in charge of a hospital detachment from the British naval force on the Danube. In 1916 he accepted an invitation to join the First British Ambulance Unit in Italy as operating surgeon. He remained attached to that unit for about fifteen months, and, acting with the Second Italian Army, had his first opportunity of seeing the realities of modern warfare. The honour of Cavalier of the Order of the Crown of Italy was conferred upon him in July, 1920. In his book entitled *Reminiscences of Three Campaigns*, published in 1919, he paid a glowing tribute to the bravery of our Italian allies

In the course of his long and busy career Sir Alexander Ogston received many honours. He was Surgeon in Ordinary in Scotland successively to Queen Victoria, King Edward VII, and King George V. In 1901 the University of Glasgow, on the occasion of its 450th anniversary celebrations, conferred on him the honorary degree of LL.D., and in 1910 his own university paid him the same honour. In 1902 he was appointed to the Royal Commission on Physical Training in Scottish Schools; he was a member of the Deutsche Gesellschaft für Chirurgie, and a corresponding member of the Société Royale des Sciences Médicales et Naturelles of Brussels. In 1912 his name appeared in the Birthday Honours List as Knight Commander of the Royal Victorian Order.

As far back as 1873 he was secretary of the Section of Surgery at the Annual Meeting of the British Medical Association in London, being its vice-president when it met in Dublin in 1887, and president at Carlisle in 1896; in 1889 he delivered the Address in Surgery when the Association met at Leeds. By the choice of his local colleagues he held office as President of the Association when the Annual Meeting was held at Aberdeen in July, 1914, and since 1922 he had been a Vice-President of the Association. His active work for the Association included membership of the Parliamentary Bills Committee in 1889–1901; presidency of the Aberdeen Branch in 1900, and again from 1915 to 1919; and membership of the Aberdeen Branch Council in 1920.

Between the years 1868 and 1902 Alexander Ogston contributed a large series of original papers to British and Continental medical journals. Among the most noteworthy of these contributions may be mentioned: The Operative Treatment of Genu Valgum (*Edinburgh Medical Journal*, 1876–77); The Growth and Maintenance of the Articular

Ends of Adult Bones (*Journal of Anatomy and Physiology*, 1878); Report upon Micro-organisms in Surgical Diseases (*British Medical Journal*, 1881); Micrococcus Poisoning (*Journal of Anatomy and Physiology*, 1882); Continental Criticism of English Rifle Bullets (*British Medical Journal*, 1899); and A New Principle of Curing Club-foot (*British Medical Journal*, 1902).

Sir Alexander Ogston was twice married, his first wife being Mary Jane, daughter of Mr. James Hargreave, and his second wife Isabella Margaret, daughter of the late Provost James Matthews of Springhill. By his first wife he had two sons and two daughters, and by his second wife four sons and four daughters. He is survived by two sons and five daughters.

We are indebted to Sir JOHN MARNOCH, Regius Professor of Surgery, University of Aberdeen, for the following tribute:

It is almost twenty years since Sir Alexander Ogston resigned the chair of surgery in Aberdeen, and for a number of years prior to that he had ceased to be surgeon to the Infirmary. To the present generation of students, therefore, he is known only by name, but upon those of us who had the privilege of being his pupils when he was at the zenith of his career as a surgeon and teacher he made a profound impression. He was the most outstanding personality in the University.

At the time I am thinking of, in the late eighties, his researches into the cause of suppuration had earned for him a world-wide reputation, and it was therefore with great reverence, not unmingled with awe, an awe that lingered with us even in later years, that we approached him as the great master of the science and art which we had chosen to learn. His great powers of deft and graphic description made his lectures delightful to listen to. They were delivered in a slow, deliberate manner, but as he never used an unnecessary word and never repeated himself, it was only when one commenced to take them down that one realized how rapidly he covered the ground. He was greatly influenced by the German surgery of his time, and many were the German authorities that he quoted. His course of systematic surgery was much in advance of anything found in the standard textbooks of the day.

But it was in the wards and operating theatre that he was at his greatest. To watch the scrupulous care with which he went over a case, to listen to the logical analysis of the symptoms leading to a diagnosis, was a great education. His manner was as gentle and considerate to the poorest patient as to the richest. One of his great tenets was never to hurt a patient unnecessarily, and his gentle handling of a case was a fine object lesson. The operating theatre was a shrine at which we all worshipped. When a major operation was to be performed the benches were crowded—not that we always saw much, for he clung for long to the antiseptic spray, so that before the operation was far advanced the well of the theatre was shrouded in a mist. He believed in many student assistants, largely, I think, from an educative point of view. One assisted the anaesthetist, one held a basin and sponges, one manipulated the spray, and so on, and woe betide the assistant who lapsed in his duty. The short, sharp word of reproof was not likely to be forgotten. As a great pioneer and believer in the antiseptic system, he could not tolerate the slightest deviation from his ideals. His tenacity of purpose and fine results brought him great fame, and soon convinced the profession of the soundness of the system, for even in those days it could not be said that Lister's methods had gained universal acceptance. Operative technique has developed since then, but the great underlying principles are the same, and the work of pioneers like Ogston laid our modern methods on a sure foundation.

Nature had gifted him with a fine brain, but she had also endowed him with an imposing frame. The tall, commanding figure, the sparing sentences deliberately uttered, and an almost old-world courtesy combined to make up a personality not easily forgotten.

Professor T. WARDROP GRIFFITH, C.M.G., Emeritus Professor of Medicine, University of Leeds, sends this personal appreciation:

The death of Sir Alexander Ogston will cause an immense number of graduates of Aberdeen University to recall times of long ago. Many will remember him as the regius professor of surgery; others, like myself, will carry their minds back to a period prior to 1882, when he was appointed as Professor Pirrie's successor, and when his relationship with the students was only through his position as honorary surgeon to the Aberdeen Royal Infirmary. I was his dresser in 1880 and in 1881, but I can remember him long before this, because when I was a lad he operated upon my father for cataract in 1871. At that time he did a good deal of eye work, and I remember hearing my father quote Argyll Robertson, whom he had gone to Edinburgh to consult, as having said, "There is no need to go out of Aberdeen for an operation of this kind when you have a man like young Ogston." Yes, it was by the name of "young" Ogston that I first heard him referred to, and in some sense it seems not altogether absurd, because eleven years after this date I attended the lectures of his father on medical jurisprudence. Alexander Ogston retained his wonderful physique and youthful appearance till late in life. I well remember a visit he paid to Leeds some eighteen years ago; he had come to attend the dinner of the West Riding Aberdeen University Club, and we spent a day at the Leeds Infirmary, of which, and of its surgery, he had such a high opinion. I introduced him to a good many of my colleagues, but I had serious difficulty in making them understand that this was really *the* Ogston—the "genu valgum" man, as they termed it. They thought it must be his son! I had to emphasize that this was veritably *the* Ogston whom they had in their minds, the deviser of the ingenious operation for genu valgum, the ardent and early disciple of Lister, and the first man to demonstrate the invariable presence of micrococci in an acute abscess. I remember that I had a great treat for him during his visit. Many years before Mr Jessop had operated on a young man for double genu valgum, and, as he sometimes did, he performed Ogston's operation on the one side and Macewen's on the other. A good many years afterwards the man died, and I managed to secure enough of the two legs to show the excellent result which was obtained on the two sides and between which there was nothing to choose from the point of success. The specimens, which are now in our museum, I kept unmounted for a good many years in the hope that some day I might have the pleasure of showing them to my dear old master, and not without a hope that they might act as a bait to attract him to Leeds. I well remember the avidity with which he took off his coat, turned his cuffs up, and "sat down to" the two specimens. He used to tell us that he regarded Macewen's operation as the better of the two. "Personally," he used to say, "I get as good results with the one as with the other, but I should certainly recommend Macewen's operation as preferable to my own." I remember hearing Mr. Jessop say that he had been greatly impressed by a statement to this effect which he had heard Ogston make at some big discussion on the subject; his comment was, "There spoke an honest man." Like many surgeons, he had a sort of mild, good-natured contempt for the art of medicine, well illustrated by the following incident, of which, to his great amusement, I reminded him some thirty years after its occurrence. Dr. A. W. Russell—and we talked about it the other day when we met—was his chief dresser, and they were going round together fixing up the operations for the next morning; his attention was called to one lad who was due for operation, but who had "some kind of a rash." When he saw the lad he remarked, "Chicken-pox, Russell," with that slight emphasis on the second word which any of his old students would certainly give to if they were recounting the incident, and by expression to if they were recounting the incident, and by was passing on when Russell said, "What shall I give him, Sir?" After a slight pause Ogston quietly said, "Give him a stick of barley sugar."

Yes, Ogston was a great man, a glutton for work, painstaking, unsparing of himself, and very thoughtful

He was an admirable teacher, and I think the part of his teaching that impressed me most was that which he gave us in the small out-patient department. The work was leisurely and, the number of patients being small, it was very thorough. He used to think out his ingenious orthopaedic operations, and tell us exactly what he was going to do, and there is no doubt that his results were excellent.

The death of Ogston closes a chapter in the history of the University and Infirmary of Aberdeen; it will at the same time cause a great many of his former students not only to call to mind an old teacher with feelings of admiration, respect, and affection, but it will remind them of each other and strengthen that bond of fellowship which should, and which does, exist between those who have been trained at the same school.

Dr. E. A. CHILL (Battle, Sussex) writes:

May I add my tribute of appreciation for the courtesy, humility, kindliness, and loyalty which animated this distinguished surgeon. In 1914 Sir Alexander Ogston was surgeon to H.M. the King in Scotland, and also President of the British Medical Association, and yet on the outbreak of war, and at the age of 69, he consented to leave his well-earned retirement in Aberdeen, and come to London to act as consulting operating surgeon at a small auxiliary military hospital at Southall, Middlesex. His presence soon made itself felt in various directions, and with an up-to-date operating theatre, and assisted by a capable staff of surgeons and nurses infected by his enthusiasm, the hospital was permitted by the military authorities to receive the seriously wounded direct from France or Flanders. While he was with us we received a visit from the late Editor of the *British Medical Journal*, and as a result an account of our work appeared from the pen of Sir Dawson Williams. As organizer and administrator of the hospital I feel it incumbent to place on record Sir Alexander Ogston's work among us. He was a great surgeon and a great gentleman. He was modest even to shyness, but had the gift of winning the esteem and affection of all those with whom he came in contact.

W. E. H. writes:

Not one of his many dressers, clerks, or house-surgeons who to-day mourn the passing of their chief can ever forget Ogston in his operating theatre or in his wards. We recall his methodical and unhurried progress from bed to bed, his intense concentration on the examination of the case, and his kindly consideration for the patient. In the dark ages before *x* rays were available it was a memorable object-lesson to see him conducting the investigation of some obscure hip-joint condition, as in clear and deliberate tones he dictated to his clerk the results of measurements, tests, and range of movements. It was in the days before *x* rays that he worked out the condition coxa vara. A pioneer in orthopaedic surgery, the rare quality of his operative work was the outcome of careful thought expended beforehand on the whole procedure of his operations, for his great manipulative skill went hand-in-hand with a sound and sagacious judgement.

We knew our chief was an Olympian, and so we were not surprised when to his operating theatre came surgeons from many lands. The writer remembers well how, early one Sunday morning, he was summoned to the chief's room, and there was introduced to a famous knight of surgery from Dublin. "Let me introduce you," said Ogston, "to the man who first tied the internal iliac artery. Nevertheless he has a gumboil. Bring me a history." Do we not also recall his quaint, old-world phraseology in his lectures as professor of surgery, and his sly digs at the "armchair theorists"? "More ink than blood has been shed on this point," was how he summed up the alleged terrors of an abnormally distributed artery. In Alexander Ogston a great surgeon and a great man has passed to the other side.

[The photograph of Sir Alexander Ogston reproduced at page 325 is by R. M. Morgan, Ltd., Aberdeen.]

JOHN EDWIN EDDISON, M.D.,

Emeritus Professor of Medicine, University of Leeds; Consulting Physician, Leeds Infirmary.

We have to record with great regret the death of Dr. J. E. Eddison, formerly of Leeds, which occurred on January 27th at Cuckfield, Sussex, where he had gone to live some few years ago. John Edwin Eddison, who belonged to a well-known Leeds family, his father being a member of an old-established firm of solicitors, was born in 1842. He graduated M.D. at Edinburgh, and often said that the selection of Edinburgh as his medical school was a very deliberate choice on the part of his father, who was of opinion that at that time the teaching was better there than could be found elsewhere. He supplemented his Edinburgh training by spending some time at St. Bartholomew's Hospital, and became a Member of the Royal College of Surgeons of England in the same year that he graduated at Edinburgh—namely, in 1864. After spending a year or two in Paris and Vienna he commenced practice in Leeds, and in 1871 a vacancy on the staff of the General Infirmary, caused by the resignation of the late Dr. Chadwick, led to his being appointed physician as junior colleague to Dr. Heaton and Dr. Clifford Allbutt. He served the Infirmary as full physician till 1892, when he became a member of the consulting staff. His work, however, was not confined to this, the greatest of the Leeds hospitals, for he was physician to the Public Dispensary, to the Women and Children's Hospital, and to the Leeds "House of Recovery," or Fever Hospital, where he was associated with the pioneer work of Allbutt. He also took a great interest in the founding of the Leeds Trained Nurses' Institution, which dates from 1875, and acted as its honorary consulting physician.

When Eddison began practice in Leeds great changes, some only of which were apparent to the multitude, were imminent. The old Leeds School of Medicine, instituted by the first William Hey in 1831, was run very much on the lines of a limited liability company, and had for many years been doing excellent work. When the Yorkshire College of Science was started (with, it is often said, three professors and one student) an arrangement was entered into by the school of medicine that the preliminary scientific subjects of medical education should be taught at the new institution. From this small beginning arose the great developments now in progress in connexion with the University of Leeds. The Yorkshire College of Science dropped its qualifying words, becoming simply the Yorkshire College, and instituted chairs of Latin and Greek, widening its outlook in many other respects. In 1884 the old medical school amalgamated with the Yorkshire College, which in this and in other ways attained to university status, and was admitted as the third college of the federal university known as the Victoria University, with its seat in Manchester. The subsequent developments are fresh in the minds of all. Though the old Victoria University was doing great work, the federal system was attended with some disadvantages, and a desire for greater freedom and independence resulted in the formation of the three universities of Manchester, Liverpool, and Leeds in 1903. Dr. Eddison was very closely associated with all these changes, and at the "coming of age" of the University in 1924 he was awarded the honorary degree of doctor of science. Early in his career he became associated with Dr. Allbutt in the joint lectureship in medicine, and he was the first professor of medicine in Leeds after the affiliation of the Yorkshire College with the Victoria University. Both in his work as a lecturer and as a clinician he always showed something original and arresting in his teaching. Frankly, it was not the kind of teaching which was adapted to the requirements of the average student; it was not didactic. He was possessed of a mind so critical, so alert, and so trained to the exposure of fallacies that to many he seemed to take much more pleasure in pointing out what was not the case than in trying to impress on his students the well-established facts upon which their future professional work would have to be based. The writer formed the opinion many years ago that this characteristic of his teaching sprang not only from his critical outlook

on things in general, but from a deliberate conviction that the work of a teacher in a subject like medicine ought to place the mere imparting of information on a plane altogether below that which deals with the stimulation of the minds of his students so that they may be guided to learn for themselves. If the average student, therefore, was somewhat discouraged by his teaching, many will have discovered by now that he taught them a great deal more than they felt at the time; those who acted as his resident officers, and were old enough to attain to some understanding of his outlook, learned a great deal by their association with him in the wards of the Infirmary, and will always cherish the recollection of a kind and considerate master.

Dr. Eddison was for many years a member of the British Medical Association, and served on the Central Council from 1910 to 1912. He was one of the original members of the Leeds and West Riding Medico-Chirurgical Society, founded in 1872, and was president in the session 1882–83; he never lost his interest in its work, but attended the meetings with great regularity until his final retirement from practice in 1907. There must be many who, with the writer of these lines, can recall his ready and fascinating oratory and his shrewd wisdom—at times only too successfully concealed by a whimsical and humorous presentation of his case. Outside his professional life he was a man of very wide interests. He was a great reader, and in this respect his tastes were catholic, and he was for many years a very strong supporter of the Leeds Literary and Philosophical Society. He was president four times, and when he was elected to the council in 1919 it was pointed out that this was the fiftieth successive occasion on which he had been elected to this position. As already mentioned, he retired from his professional work, which for many years had been strictly limited to that of a consulting physician, in 1907. He went to live at Cuckfield in Sussex a few years ago. The interment was in Adel Churchyard, close to where Dr. Eddison had lived for so many years; the service was conducted by the vicar of the parish and by his old friend, Dr. Draper, the Master of the Temple. Among those present at the funeral were representatives of the University of Leeds and the Infirmary, and of other societies with which he was associated, including the Medical Charitable Society for the West Riding of the County of York, for which he did such excellent work, and many of his professional brethren.

T. W. G.

C. G. DRUMMOND MORIER, L.R.C.P. AND S.I.

DR. C. G. DRUMMOND MORIER died on February 2nd. He was born in 1856, and received his medical education at the school of the Royal College of Surgeons in Ireland, Charing Cross Hospital Medical School, and Vienna. In 1880 he became L.M. Rotunda Hospital, Dublin, and L.R.C.P. and S.I. in 1883. He was at one time medical officer of the Nairne and Mount Barker districts, South Australia. He was for many years a member of the British Medical Association, and was the representative of the Adelaide and South Australian Branch on the Central Council from 1898 to 1914, when he was succeeded by the late Dr. W. T. Hayward; he was also an ex-chairman of the Dominions Committee of the Association. Dr. Morier was a Fellow of the Royal Society of Medicine and a member of the Society for the Study of Inebriety.

C. O. H. writes: Charles George Drummond Morier, who died on February 2nd, brought to the practice of medicine an exceptionally virile and effective personality. In mind, as in physique, he was every inch a man, and his readiness and ability to carry responsibilities, associated as this quality was with a particularly shrewd judgement and much kindness of heart, made him for many a help and stay in anxious and difficult hours. His social gifts secured for him many friendships, and to these he held in all loyalty and practical service. Those of us who shared with him many experiences and memories recall gratefully his good comradeship, and regret the loss of one who knew the rules of the game, and ever followed them with unfailing sincerity and courage and goodwill.

A memorial service was held at St. Mark's Chur Hamilton Terrace, N.W., on February 6th, at wh Mr. H. M. Stratford, F.R.C.S.Ed., the honorary secretr of the Kensington Division, represented the Council the Association, and the interment subsequently took pl at Farnham Royal, Bucks.

PIERO GIACOSA, M.D.,

Professor of Pharmacology in the University of Turin.

For the following appreciation of the late Professor Giac of Turin we are indebted to Professor Arturo Castiglic of Trieste.

The death of Piero Giacosa has come as a most painf loss, not only to the medical profession in Italy in which occupied so distinguished a position, but to all who lov in him the scientist, the great teacher, and brilliant write and appreciated the gifts of his character and mind. Bo at Parella, near Ivrea in Piedmont, in 1853, of a fami distinguished for its learning, he was the younger broth of Giuseppe Giacosa, one of the best-known writers a authors of plays of the end of last century in Italy. Pie Giacosa devoted himself to the study of medicine at Turi where he graduated in 1876. Even in his first medic research concerning the physiology of respiration at hig altitudes, Giacosa displayed his powers as an acute observe He continued his studies in Strasbourg at the physiologic institute of Hoppe-Seyler, then at Berne and Erlange where he became the assistant to Lenbe. In 1881 he becam assistant to Angelo Mosso at the physiological school o the University of Turin; he was next appointed lecture in pharmacology and director of the laboratory of experi mental pharmacology. In 1894 he was elected to the chair which he occupied without interruption until 1928. H was the author of a treatise on materia medica, pharmaco logy, and toxicology, which became a standard work by reason of the vast knowledge it contained of chemistry biology, and medicine; it is to Giacosa that we owe the beginnings of the important researches into the oxidation of aromatic hydrocarbons in the organism and into the transformation of nitrates. He was also the author of epoch-making investigations into the history of medicine. His work entitled *Magistri Salernitani nondum cogniti*, in which he brought together a large number of texts of the ancient Masters of the "Studium" of Salerno, cast a new light on the history of that medical school in the Middle Ages. He was in close friendship with the greatest men of science of his time; a mark of the esteem he enjoyed abroad was the degree of Doctor *honoris causa* conferred on him by the University of Cambridge. His vast and many-sided labours, his kindness of heart, and the excellence of his teaching will assure him the grateful and heartfelt remembrance of students beyond the confines of his own country.

THE LATE DR. F. DE HAVILLAND HALL.

SIR FRANCIS CHAMPNEYS, Bt., writes: May I add a few words to the obituary notice of Dr. de Havilland Hall which you have published? I have known him well for half a century, and was intimately associated with him for a good many years during the foundation and early history of St. Luke's Hostel for Clergy. He was one of the kindest and most charitable men that I ever knew. I do not suppose that anyone was more often consulted by members of his own profession for themselves or for their families and he never failed them. I consider that this is one of the best rewards that a medical man can gain. In the work that he undertook he never spared himself, and I never put himself forward. In criticism of others he set an example of charity. I should think that he had few enemies, and that few men can have led so long a life without reproach.

Lieut.-Colonel C. SAMMAN, Master of the Society of Apothecaries of London, writes: I have read the obituary notice of Dr. de Havilland Hall in the *Journal* with great interest, and think your readers may like to know that in addition to his many other activities he was a prominent member of the Court of Assistants of this Society, whose valued opinions and advice, so courteously expressed, were

always listened to with great respect by his fellow members of the court. I, as Master, Mr. Osborn, and Mr. Adams Frost, members of the court, and Dr. Haydon, secretary to the Court of Examiners, were present at the funeral at Twickenham.

We regret to announce the death, at the age of 63, of Dr. LEO FERDINANDO BIANCHI, F.R.C.P.Ed., F.R.C.S.Ed., which occurred at his home in Portobello, Edinburgh, on January 17th. Dr. Bianchi was born at Tunbridge Wells in March, 1865, and was educated at St. Augustine's College, Ramsgate, and then aboard the Thames Nautical Training College, H.M.S. *Worcester*, off Greenhithe, Kent. In 1885 he was appointed a midshipman in the Royal Naval Reserve and served in the Hooghly Bengal Pilot Service. He had the honour of being among the five candidates chosen to receive Her Majesty Queen Victoria's gold medal for the boy likely to make the finest sailor. The Indian climate told on his health, and he was retired from the pilot service with a pension. Some time after returning to Edinburgh he decided to engage in medical studies as a hobby, and he obtained the diplomas L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas. in 1904. In 1905 he became M.R.C.P.Ed., and received the D.P.H. R.C.P.S.Ed., and in 1908 he obtained the F.R.C.S.Ed. For a time he held an appointment as non-resident house-physician at the Royal Infirmary, Edinburgh; he subsequently started private practice in Joppa, and later in Portobello. In 1920 he obtained the Fellowship of the Royal College of Physicians, Edinburgh. He was a member of the British Medical Association from the date of his qualification in 1904, and from 1916 to 1919 was on the executive committee of the Edinburgh Division. Dr. Thomas I. Mills writes: Dr. Bianchi and I have been close friends both as seamen and as members of the medical profession for forty-seven years. He was a man of fine character and a natural leader of men.

Colonel JOHN ARNALLT JONES of Llandaff, Cardiff, who died last December, was born in June, 1852, and received his medical education at the London Hospital. He obtained the diplomas L.S.A. in 1884, L.R.C.P.Lond. in 1885, M.R.C.S.Eng. in 1887, and D.P.H. in 1904; he graduated M.D.Durh. in 1902. For many years he was medical officer of health for the Borough of Aberavon and Swansea (Port Talbot) Sanitary Authority. While at Aberavon he was instrumental in the formation of ambulance classes for the local railwaymen and other workers. He took great interest in the Volunteer movement, and became colonel of the 2nd V.B. Welch Regiment. During the last war Colonel Arnallt Jones served in the Dardanelles as A.D.M.S. to the 53rd Welsh Division, and in 1922 became honorary colonel R.A.M.C., Welsh Division, in succession to the late Sir John Williams. He was an honorary surgeon to the King. He was appointed J.P. for county Glamorgan, and a Justice in Lunacy. Colonel Arnallt Jones was a member and ex-chairman of the Swansea Division of the British Medical Association, and was secretary of the Section of Navy, Army, and Ambulance when the Association held its annual meeting in Swansea in 1903. He was an enthusiastic worker for the Priory for Wales of the Order of the Hospital of St. John of Jerusalem, and for his services the distinction of Knight of Grace of the Order was conferred upon him. He leaves a widow and one daughter.

DR BERTRAM ADDENBROOKE, whose death from acute pleurisy and pulmonary embolism occurred at his home at Kidderminster on January 22nd, had been in practice in that town for about thirty years, having joined his father, the late Dr. Edward Homfray Addenbrooke, there in 1898. Born in 1874, he received his medical education at Mason College, Birmingham, and Newcastle-on-Tyne, and in 1896 he obtained the diplomas M.R.C.S.Eng. and L.R.C.P.Lond., and graduated M.B., B.S.Durh., proceeding M.D. three years later, after having graduated B.Hy. He had held various resident posts in Birmingham previous to joining his father in practice at Kidderminster, where he speedily gained distinction among his fellow practitioners and became very popular. He held a number of public medical appointments, including that of honorary surgeon to the Kidderminster General Hospital; he was also medical officer of health for the Kidderminster Rural District. Dr. Addenbrooke was keenly interested in the Volunteer movement and its successor, the Territorial Army, in which he held a commission in the R.A.M.C. At the outbreak of war he volunteered for active service, and early in 1915 went to France with the 7th Battalion, Worcester Regiment. Six months later he was transferred to the 12th General Hospital at Rouen, where he was for a time surgical specialist. He was demobilized on account of ill health in 1917, and a few years ago he retired from the Territorial Army after having reached the rank of major and having received the Territorial Decoration. He was a Fellow of the Royal Institute of Public Health. A keen member of the British Medical Association, he served on the Council of the Worcester and Hereford Branch from 1910 to 1914 and from 1920 to 1925; in 1923 and 1924 he was successively vice-chairman and chairman of the Worcester Division. The death of Dr. Addenbrooke, after a very short illness, came as a painful shock to his many patients and friends, a very large number of whom, including nearly all the medical practitioners of the district, were present at his funeral on January 25th. He leaves a widow and one daughter.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on February 8th the following medical degrees were conferred:

M.B., B.CHIR.—F. H. Gillett.
B.CHIR.—D. B. Wilson.

Dr. T. S. Hele has been appointed a member of the M.B. Degree Committee, in place of Sir F. G. Hopkins, resigned.

UNIVERSITY OF LONDON.

THE report from the Committee on the Medical Education of Women Undergraduates has been generally approved by the Senate and the recommendations appended thereto have been adopted (an abstract of the report was published in our issue of February 2nd, p. 217).

The regulations for the M.S. Examination, Branch III (Ophthalmology) have been amended by the substitution for the third paragraph on p. 254 of the Red Book, 1928-29, and on p. 241 of the Blue Book, September, 1928, of the following:

Every candidate must forward together with his form of entry the following certificates: (i) A certificate of having spent a total period of at least two years in the study and practice of ophthalmology at a teaching school or schools approved by the University, of which one year at least must have been subsequent to obtaining the M.B. B.S. degrees in this University. (ii) A certificate that, in the course of this period of two years, he has held for at least six months an approved appointment in the ophthalmic department of a general hospital recognized by the University for the purpose, or at an ophthalmic hospital recognized by the University, without ceasing to attend, for the purposes of the study and practice of ophthalmology, a teaching school or schools approved by the University.

The regulations for the M.S. examination, Branch IV (Laryngology, Otology, and Rhinology), Red Book, 1928-29, p. 255, and Blue Book, September, 1928, p. 242, have been similarly amended.

An Academic Diploma in Clinical Pathology is to be instituted, the regulations for which will be obtainable in due course from the Academic Registrar.

Applications for grants from the Thomas Smythe Hughes Medical Research Fund for assisting original medical research must be received not earlier than May 1st and not later than June 15th, 1929. Particulars may be obtained from the Academic Registrar.

A University Studentship in Physiology of the value of £100 for one year will be awarded to a student qualified to undertake research in physiology, if a candidate of sufficient merit shall present himself. Applications must be received by the Principal Officer by May 31st. Full regulations of the award can be obtained on application.

Dr. H. Gainsborough has been recognized as a teacher of the University in Medicine at St. George's Hospital Medical School.

The following have been appointed staff examiners in the subjects of examinations for medical degrees for 1929:

Anatomy.—Professor T. H. Bryce, F.R.S., and Professor Mary F. L. Keene.
Bacteriology.—Major General D. Harvey, C.M.G.
Chemistry.—First Medical: F. D. Chattaway and Miss Sybil T. Widdows. Second Medical: F. D. Chattaway and Professor J. C. Drummond.
Forensic Medicine and Hygiene.—W. B. Anderson and A. S. MacNalty.
General Biology.—F. Drabble and Miss Phil pps C. Esdaile.
Medicine.—Professor A. J. Hall, C. Wall (internal), C. E. Lakin (internal), and Professor H. MacLean. As oc ate Examiners: D. H. de Souza, Professor W. E. Hume, Profe sor A. W. M. Ellis, and J. A. Ryle.
Mental Diseases and Psychology.—E. D. Mc namara and C. W. B. James.
Neurology.—T. M. Hinds Howell and W. J. Adie.
Obstetric Medicine.—Professor M. H. Phillips and J. B. Banister. Associate Examiners: D. W. Boy and I. D. Bar is.
Oto-Rhino-Laryngology.—Sir William M'Ewen and Herbert Tilley.
Pathology.—Professor E. J. Kettle and Professor J. M. Beattie. Associate Examiners: R. Donaldson and J. A. B. Hicks.

Pharmacology.—Professor W. E. Dixon, F.R.S., and V. J. Woolley.
Physic.—G. Stead and Professor J. A. Crowther.
Physiology.—Professor J. B. Leathes, F.R.S., and Professor J. Mellanby.
State Medicine.—R. A. Lyster and G. F. Buchan.
Surgery.—H. S. Souttar, Professor C. A. Pannett (internal), W. Girling Ball (internal), E. C. Hughes, and as fifth examiner if required, C. M. Page, D.S.O. Associate Examiners: G. T. Mullally, P. H. Mitchiner, E. K. Martin, W. H. Hey, and as fifth examiner if required, R. M. Vick.
Tropical Medicine.—J. B. Christopherson.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Division of Tropical Medicine and Hygiene.

The following passed the examination at the termination of the eighty-fifth session (October, 1928, to February, 1929).

*S. Batchelor (Duncan medal), *T. C. Backhouse, *J. Bryant, *L. S. Chatterji, *R. S. F. Hennessey, *M. Howitson, *W. S. Nealor, *A. J. W. Wilkins, C. M. Africa, K. P. Anklesaria, E. A. Aslett, F. C. K. Austin, D. C. Bell, P. S. B[illegible] Brown, J. A. Carman, I. E. Chandler, A. D. C[illegible] Chopra, J. C. Chukerbuti, A. H. Craig, M. D[illegible] Dodds, A. N. Duggal, A. L. Goddard, J. G. Green, H. E. Hargreaves, E. Haworth, W. Hunter, H. Joomye, N. Kamchorn, C. Libert, L. S. Liu, S. I. McMillen, A. Moorns, G. M. M. Menzies, G. W. Milledge, G. E. G. Nunns, N. M. Rane, S. L. Rikhye, J. S. Robinson, S. F. Russell, I. A. Senanayeke, E. H. Stahly, R. Stanford, E. M. Turner, F. B. Turner, O. R. Unger, A. E. S. Whatron, E. W. Whitcomb, C. D. Williams, D. B. Wilson.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on February 5th, when the president, Dr. Robert A. Fleming, was in the chair.

Dr. James Davidson Stuart Cameron (Edinburgh) and Dr. Archibald Nathaniel Shirley Carmichael (Edinburgh) were introduced and took their seats as Fellows of the College. Dr. Ella Ferrier Pringle (Edinburgh) and Dr. John Miller Woodburn Morison (Edinburgh), were elected Fellows of the College.

Dr. William Sidney Thayer, Emeritus Professor of Medicine of the Johns Hopkins Medical School, Baltimore, U.S.A., was appointed Gibson Lecturer for the triennial period 1929-31.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel Thomas MacDermott, O.B.E., R.A.M.C.(ret.), died at Cheltenham on January 22nd, aged 63. He was born in Ireland on November 1st, 1865, and was educated in the Catholic University, Dublin, graduating as B.A., M.B., Ch.B., and B.A.O. in the Royal University of Ireland in 1889. Entering the R.A.M.C. as surgeon lieutenant on July 27th, 1892, he attained the rank of lieutenant-colonel on November 27th, 1914, retiring on November 1st, 1920. He served throughout the South African war of 1899-1902, when he took part in the operations in Natal in 1899-1900, including the action at Talana, the defence of Ladysmith, and the action at Laing's Nek; and in the Transvaal in 1900-2, including the actions at Belfast and Lydenbergh; and received the Queen's medal with four clasps and the King's medal with two clasps.

Major Henry Daniel James, R.A.M.C.(ret.), died at St. Leonards on January 22nd, aged 71. He was born at Multan on June 20th, 1857, the only son of the late Rev. H. D. James, M.A., chaplain, Bengal Presidency, and vicar of Hambledon, Oakham, and was educated at King's College, London, where he was resident Warneford scholar. He took the L.S.A. in 1883, the M.R.C.S. in 1884, and the L.R.C.P. Lond. in 1891. Entering the army as surgeon on January 31st, 1885, he became surgeon major after twelve years' service, and retired on January 31st, 1905. He served on the North-West Frontier of India, in the campaigns of 1897-98, taking part in the operations on the Samana Range (medal with two clasps), and through the Tirah campaign, at the actions of Chagru Kotal and Dargai, the capture of the Sampagha and Arhanga Passes, the reconnaissance of Sarau Sar, and the operations in the Bara Valley (clasp); and in the South African war in 1899-1901, in operations in the Transvaal, Orange River Colony, and Cape Colony (Queen's medal with four clasps). He also rejoined for service in the great war, and served in the South of Ireland for two years, 1915-17. Major James was a member of the British Medical Association, and represented the Hastings Division at the Annual Representative Meeting of the Association at Portsmouth in 1923.

Major Alfred Herbert Heslop, D.S.O., O.B.E., R.A.M.C. (ret.), died at the Clergy House, Exeter, on January 30th, aged 48. He was born on March 5th, 1880, the younger son of the late Rev. R. C. Heslop of Wakefield, and was educated at St. Thomas's Hospital and at Durham University, where he graduated M.B. and B.S. in 1903. Subsequently he took the F.R.C.S. in 1921. After filling the posts of house-surgeon at the Salop Infirmary, Shrewsbury, and the Durham County Hospital, and of clinical assistant at All Saints' Hospital for Genito-Urinary Diseases in Vauxhall Bridge Road, London, he entered the R.A.M.C. as lieutenant on July 30th, 1906, became major after twelve years' service, and retired on October 2nd, 1926. After retiring from the army he went into practice at Ryde, Isle of Wight, where he was surgeon to the Royal Isle of Wight County Hospital at Ryde, and consulting surgeon to the King Edward VII Convalescent Home for Officers at Osborne. He served in the recent great war, when he was four times mentioned in dispatches, in the *London Gazette* of January 1st, 1916, June 15th, 1916, December 24th, 1917, and May 25th, 1918, and received the D.S.O. in 1916 and the O.B.E. in 1919. He married Florence Madelaine, daughter of H. W. A. Walker, Esq., and leaves one son and one daughter.

Medical News.

A MEETING of the Royal Microscopical Society will be held at 20, Hanover Square, W.1, on February 20th, at 8 p.m. The effects of certain agencies on cell division *in vitro* will be discussed, Dr. R. G. Canti and Mr. F. G. Spear dealing with radium, Mr. S. F. Cox with *x* rays, and Mr. F. G. Spear with low temperature in this respect. Demonstrations will be given by Mr. S. F. Cox on the effect of a heavy dose of *x* rays on living cells as shown by the dark-ground method, and by Dr. Canti on cell division in the living tissues cultivated *in vitro*. Stained preparations will be exhibited to indicate the effects of radium, *x* rays, and low temperature on cell division.

UNDER the auspices of the National Council for Mental Hygiene Dr. Letitia Fairfield, C.B.E., will deliver a lecture on "Efficiency and deficiency" at the rooms of the Medical Society of London, 11, Chandos Street, W.1, on Wednesday, February 20th, at 5 p.m.

THE annual meeting of the Industrial Health Education Society will be held at 4 p.m. on Tuesday, February 19th, in the board room of the Society of Medical Officers of Health at 1, Upper Montague Street, Russell Square, London, with Sir Humphry Rolleston, the honorary president, in the chair. The speakers will be Lord Melchett, on behalf of employers, and Mr. Ben Tillett, president of the Trade Union Congress, on behalf of the employees. A brief account of the activities of the society was given in the *Journal* on January 26th (p. 183), when it was stated that a public appeal was being made for £5,000 to enable its work to be maintained and expanded to meet the demands made upon it.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that a lecture on "Pitfalls in dermatology" will be given by Dr. A. C. Roxburgh on Monday, February 18th, at 5 p.m., at the Medical Society, 11, Chandos Street, Cavendish Square. On the following day, at 10.30 a.m., at the National Heart Hospital, Dr. B. T. Parsons-Smith will give a clinical demonstration. At the Wellcome Museum of Medical Science, 33, Gordon Street, Dr. C. M. Wenyon will give a demonstration on the part played by animals in the spread of disease; on Wednesday, February 20th, at 4 p.m., and on Thursday, February 21st, at 2 p.m., Mr. Gill-Carey will give a clinical demonstration at the Central London Throat, Nose, and Ear Hospital. There are no fees for the above lectures and demonstrations. From February 25th to March 2nd there will be an all-day course in diseases of the chest at the Brompton Hospital, and from February 25th to March 9th a morning course in diseases of children will be given at the Hospital for Sick Children, Great Ormond Street. From March 11th to 23rd an all-day course, with limited entry, will be held at the Royal National Orthopaedic Hospital, and an afternoon course in ophthalmology at the Royal Eye Hospital. Copies of all syllabuses and details of the general course, consisting of attendance at clinical practice of some forty London general and special hospitals, may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1.

THIS year, at Whitsuntide, a party of doctors and others will go on a tour of mediaeval towns and spas in Germany. Among the places to be visited are Hildesheim, Goslar, Bad Harzburg, Schierke, Bad Sachsa, Weimar, Eisenach, Kissingen, Nuremberg, Rotenburg, Wurzburg, Heidelberg, Frankfort, Bad Nauheim, Wiesbaden, Ems, Coblenz, and Cologne. The party is due to leave London on Tuesday, May 14th, and return on June 4th. The cost will be £45 12s., including all travelling expenses, meals, hotel charges, and gratuities. Wives or daughters of medical men joining the tour will be welcomed. Particulars may be had from [illegible], Henry Baerlein (Bath Club, 34, Dover Street, London, W.1), who organized the enjoyable visits to Czechoslovakia and Jugoslavia in 1927 and 1928.

SPEAKING at the Chelsea Town Hall on February 11th, Mr. Samuel Hoare announced that Lord Melchett had purchased 13 acres of land for the erection of new buildings for the

Chelsea Health Society, of which Lady Melchett is president. It is intended to set up a centre in which accommodation will be found for the various health organizations of the borough. Subsequently it was explained that the gift was associated with Lady Melchett's scheme for a children's health centre, and that she intends to build a model infant's welfare centre, babies' nursing home, and day nursery. Offices will also be provided for the Invalid Children's Aid Association, and accommodation for the London County Council school treatment centre.

AT a dinner-party given in the parlour of Apothecaries' Hall, Blackfriars, on February 12th, the guests were received by the Master, Lieut.-Colonel C. T. Samman; the Senior Warden, Dr. H. J. Hott: and Dr. T. Vincent Dickinson, Past-Master, in the absence of the Junior Warden, Sir George Buchanan. This occasion was taken to introduce formally to the Society of Apothecaries four medical men recently awarded the new diploma of Master of Midwifery after special examination in ante-natal care, child welfare, and midwifery. Among the other guests were Lieut.-General Sir Matthew Fell, Director-General A.M.S., Mr. Comyns Berkeley, and the Editor of the *British Medical Journal*.

THE Council of Epsom College will shortly elect a girl to a St. Anne's Home Scholarship of £52 a year. Candidates must be fully 7 years of age and not over 12 years of age on May 1st next, and must be orphan daughters of medical men who have been for not less than five years in independent practice in England or Wales. Application must be made by March 8th on a form to be obtained from the secretary, 49, Bedford Square, W.C.1.

THE Royal Society announces in our advertisement columns that applications for the Government grant for scientific investigation for 1929 must be received at the offices of the Royal Society by March 31st. Printed forms of application can be obtained from the Clerk to the Government Grant Committee, Royal Society, Burlington House, London, W.1.

AS announced in our advertisement pages the governors and trustees of the Tancred Studentships propose to elect, shortly after Whitsuntide, one student in physic at Gonville and Caius College, Cambridge. The annual stipend is £100. Full particulars can be obtained on application to Mr. E. T. Gurdon, 28, Lincoln's Inn Fields, W.C., clerk to the governors and trustees.

THE fifth annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation gives details of the twenty-one grants made during 1928. In the five years of its existence the Foundation has contributed seventy-three grants towards researches aiming at the solution of problems in medicine and surgery. Applications for grants to be made during the year 1929-30 should be sent before May 15th to Dr. J. C. Aub, Huntington Memorial Hospital, 635, Huntington Avenue, Boston, Massachusetts.

To the current issue of *Better Health*, a small magazine published monthly at 1d. by the Central Bureau for Health Education of the Society of Medical Officers of Health, Dr. H. B. Brackenbury contributes an article entitled "How to use your family doctor."

WE are informed that *The World's Health*, which has hitherto appeared monthly, will, during 1929, be published quarterly, commencing with the March issue.

IT is announced that Mr. Albert Levy, treasurer of the Royal Free Hospital, has given £50,000 to the fund for rebuilding the hospital's maternity department and for the promotion of research on maternal mortality. The fund was instituted eighteen months ago, when the Queen gave her support to the hospital's centenary appeal; Her Majesty has agreed that the new department should bear her name. Mr. Levy, in making his gift, has been actuated by a sense of the necessity for improving the midwifery service of the country, and of the special importance of training women students in this branch of medical work.

THE Nizam of Hyderabad has made a donation of £1,000 to the Ross Institute and Hospital for Tropical Diseases, Putney Heath.

THE Jubilee Congress of the German Balneological Society, founded in 1879, was held in Berlin from January 24th to the 29th, under the presidency of Professor Dietrich. The programme contained over 50 papers dealing with various aspects of balneology. The next congress will be held at Bad Elster in April, 1930.

UNDER the auspices of the *Revue Medicale Française* there will be a medical congress in Paris, from June 9th to the 14th, under the presidency of Professor Delbet. In addition to various lectures and practical demonstrations, excursions will be arranged to historic sites and therapeutic centres. Further information may be obtained from M. Léon Tixier, 18, Rue de Verneuil, Paris (7e).

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the *British Medical Association* and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Barillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

SOUND-PROOF DOORS.

"INQUIRER" asks for suggestions as to means of deadening sounds between the waiting-room and the consulting-room. A thick curtain having proved insufficient, he has thought of adding an extra door specially constructed to prevent the transmission of sounds.

CONSTIPATION AFTER GASTRO-JEJUNOSTOMY.

"R. M. R." asks for suggestions for treating a man, aged 61, who had a gastro-jejunostomy performed more than seven years ago. Constipation is increasing, possibly owing to colonic stasis. Several kinds of paraffin have been tried—also argyrol with phenolphthalein, tablets of aloin and strychnine and belladonna—and a variety of other medicaments, but it is very difficult to overcome the constipation. The patient is very pale and thin, and extremely sensitive to cold.

MOONSHINE?

"C. I." writes: Can any medical man inform me if the statement one hears so often from people returning from the East (hot countries) that the moon has a harmful influence on residents there, more especially if it shines on their faces when they are in bed, is true or all "moonshine"?

TREATMENT OF RHEUMATIC HEART DISEASE.

DR. A. V. RUSSELL (Llanidloes) writes: Possibly "X. Y. Z." may find my experience helpful in treating the patient mentioned on February 2nd (p. 232). Among children in hospital and in private practice who suffered from rheumatism with cardiac complications I have had many with persistent slight pyrexia and some tonsillar sepsis. In one case, at least, vaccine treatment resulted in a complete cure, but, as a rule, the association of a vaccine with a peroxide gargle and a suitable throat paint was needed. Nearly all those patients who did not respond to this treatment recovered after tonsillectomy. I use Parke Davis antirheumatic vaccine in doses graduated according to the reaction observed. My favourite throat paint is the following:

℞ Zinci chloridi ... ... gr. xx
Glycerini ... ... ʒss
Aq. ... ... ad ʒij

Sig. Apply night and morning after using a peroxide gargle.

For the gargle I use one teaspoonful of hydrogen peroxide in a wineglassful of tepid water.

INCOME TAX.

Division of Partnership Assessment.

"H. K. W." inquires as to the proper method to be applied where there has been a change in the personnel of the partnership.

*** Normally—including "H. K. W.'s" case—the change does not affect the gross amount of the assessment, which is fixed by reference to the amount of the profits of the year preceding. For instance, if D succeeds to C and the new firm becomes A B and D as from April, 1928, then that firm is assessed in the same gross amount as A B and C would have been assessed if the change had not taken place, and D has to account for tax on his fractional share of that amount less his own personal allowances.

It is, of course, true that for a time C will continue to draw cash from the partnership account and D's cash receipts will be less than his assessment. But that is the consequence of the principle that earned income is liable to assessment according to the period in which it is earned rather than that in which it is received. The same point would have arisen if D had bought a sole practice from C.

Break in Period of Appointment.

"X. Y. Z." held a hospital appointment during the period April 5th to 30th, 1926, and did not take up other work until the end of May, 1926. He "paid income tax for 1926-27," and was told that *everything was in order*, but is now being pressed to pay a small amount in respect of his earnings in April, 1926.

*** Income tax liability has always to be dealt with as for the Government's financial year—that is, for a year ending April 5th. When "X. Y. Z." dealt with his liability for the year 1926-27, therefore, the declaration which he presumably made would state his total income for the year ended April 5th, 1927. Apparently one of two things happened: either he forgot to *include his April*, 1926, earnings or the *Inspector of* taxes forgot to take them into account. In either of those cases the additional small payment now requested would *legally* be due. It is, however, possible that he was assessed on the assumption that his post-April rate of remuneration applied throughout the year ending April 5th, 1927, in which case he was over-assessed. We suggest that, as "X. Y. Z." *feels* disposed to solve the question, he might reasonably ask the Inspector to supply him with full details, showing how the tax which he paid for 1926-27 was calculated. An answer to that question should enable "X. Y. Z." to see just where he stands.

LETTERS, NOTES, ETC.

Erythema Nodosum.

DR. W. CAMAC WILKINSON (*London*, W.1) writes: With reference to Dr. G. F. Walker's remarks on erythema nodosum (February 9th, p. 266), I think that as a matter of history I pointed out the association of this condition with tuberculosis in 1901, and year by year I accumulated evidence till I came to the conclusion *that erythema nodosum was a tuberculous lesion* and nothing else. *I owe this discovery* to the constant *clinical* use of tuberculin in all doubtful lesions in any part of the body.

Treatment of Pneumonia.

DR. F. M. GARDNER-MEDWIN (St. Asaph) *writes*: Now that influenza is raging in Europe and America and the death rate from pneumonia is consequently increasing, may I once more call attention to the method of precipitating the crisis in pneumonia *by means of intramuscular injections of sodium nucleinate*, together *with neutralization of the subacidosis due to febrile* toxæmia? Details of the method were published in the *British Medical Journal*, 1924, ii, p. 49, and, with Willmore, in the *Lancet*, 1922, i, p. 116. A series of 40 consecutive cases was quoted of fulminating pneumonia so treated, in which the crisis was brought about in forty-eight hours or so, with consequent defervescence and recovery, mostly occurring during the pandemic 1918-19. Since then my series has been uninterrupted, so far as cases of lobar pneumonia in previously healthy persons, without crippling complications, is concerned. I do not claim that the treatment is always successful in the elderly and infirm, or in advanced nephritics, or in the terminal pneumonias of long-standing disease, but I do claim that it is practically always successful in cases of straight pneumonia occurring as the result of the sudden *lowering of resistance by influenza or* sudden chill, and that these cases can be saved the *debilitating strain* of the long wait for the normal crisis which so often kills them. *Let me then formulate my credo.* In influenza leucopenia diminishes *resistance*; saprophytic organisms become pathogenic; sodium nucleinate releases into the blood stream leucocytes latent in the bone narrow, increasing phagocytosis. I believe that in nearly all cases of uncomplicated pneumonia, if sufficient sodium bicarbonate and glucose is given to render the urine alkaline or neutral, and 2 c.cm. of the solution of sodium nucleinate put up by the Clinical Laboratories of Paris is injected intramuscularly *into the thigh*, that in forty-eight hours or so the temperature will fall to normal, convalescence will begin *forthwith, and the patient* will rapidly recover. Would that after six years' *crying in the wilderness* I could persuade all clinicians to give this method a *fair trial* while their patients are still viable and to give up other methods, some of which, *if used* in the very early stages, appear to give somewhat similar *results*, but in the later stages may be dangerous! Nuclein is harmless and uniform in its results; its action is independent of the duration of the disease. I am not alone in my optimism, for in the *Epitome* on April 2nd, 1927 (para. 375), there is a reference to a paper by L. E. Miller in the *South African Medical Record*, who, after using this method on 117 natives, 87 of whom had lobar pneumonia, had a death rate of only 8 per cent. Miller found this *treatment of definite assistance in terminating* lobar pneumonia quickly and successfully. I hope that practitioners who have used this treatment will give me the benefit of their opinion and their results.

Influenza and Nosophobia.

DR. W. A. MACDOWALL (Manchester) writes: It would be of interest to know whether mass suggestion has not a great deal to do with the spread of epidemic disease. It is a matter for debate whether *the present* epidemic of influenza is not as much psychological as it is bacteriological in its spread if not in its origin. The influence of the mind both in the nurture and in the destruction of dentina still remains a *terra incognita*, and there is little doubt that fear is an *important* factor in lowering the bodily resistance and in encouraging the attack upon the tissues. How great a part, then, does fear play in assisting the spread of epidemic disease, and how are its effects to be counteracted? I would suggest that a medical broadcast, either by wireless or by the press, advising the public that the present epidemic was of a mild and generally innocuous nature, and at the same time sounding a note of warning, would be of great service. The function of the medical profession in these scientific times is one of prevention as well as of cure, and much might be gained by the issue of a warning such as I have indicated.

Treatment of Influenza.

"M. M. E." writes: It may be *profitable, in view of* the present influenza epidemic, to draw the attention of readers to the excellent article by Mr. E. B. Turner in the *British Medical Journal* of July 16th, 1927. He recommends keeping the patient in bed and administering 20 grains of salicin (it would appear that sodium salicylate acts similarly) every hour for twelve hours, and then every two hours for the next twelve hours. This treatment, he says, nearly always puts an end to the attack, and also reduces the chance of infecting others. Reference may also be made to the advantage of giving one or two injections of 1 c.cm. of sodium nucleinate in the treatment of influenzal pneumonia. *The effect of nucleinate* is to double the leucocyte count in twenty-four hours, and thus, in many cases, to avert a fatal termination even when the condition might appear almost hopeless.

Coincident Shingles and Varicella.

DR. LEWIS W. REYNOLDS (High Wycombe) writes: In a man, aged 80, an attack of herpes began on December 6th, 1928, involving the distribution of the ascending and descending branches of the superficial cervical plexus of the left side. Two days later a small red papular eruption appeared on the chest and arms, soon becoming vesicular and spreading to other parts of the body. The temperature went up to 102.6° on December 10th, gradually coming down to normal on December 13th. The condition followed the ordinary course for varicella, and by December 24th the last scab came away. The original eruption on the scalp, however, took a very different course. The pain was not so severe as it often is in shingles, but it is still present and causes some distress. There is a numbed feeling of the scalp on that side, also the scabs have only just entirely disappeared, now two months from the commencement.

A Possible Cause of Death in Drowning.

IN the October issue of the *West African Medical Journal* there is a posthumous communication by Dr. W. A. Young on the subject of a possible cause of death in strong swimmers. In this it is stated that in only a few of the numerous *post-mortem* examinations on adult native fishermen and capable swimmers washed up on the shore at Accra, were *the typical signs* of drowning present—namely, water in *the lungs and stomach*. In most instances the lungs were aerated and the stomach contained no water, though it was occasionally distended. Dr. Young refers to the article by W. Russell on "Hypochlorhydria and air swallowing" in the *British Medical Journal* (1919, vol. i, p. 769), and suggests that something similar to air swallowing may occur to a strong swimmer, causing sufficient distension of the stomach to lead to functional angina pectoris. As a result of considerable experience of surf bathing, Dr. Young was led to conclude that, after taking a deep breath and diving, there is a tendency for air to enter the stomach by an act of swallowing while the body is *submerged*, resulting at times in slight nausea and loss of confidence in swimming ability. It is added that this may explain the advice not to bathe on a full stomach, the reason *being that little* or no room is thus afforded for further distension of this organ by air.

Doctors' Handwriting.

"A COUNTRY DOCTOR" writes: *Doctors* should not too readily surrender their ancient privilege of illegible *writing*. I have before me a typewritten prescription *from* a physician on the *full staff of* a big teaching hospital, in which *prescription* there are six mistakes in Latin.

WE are informed that the office address of Messrs. Armour & Co., Ltd., is now Armour House, St. Martin's-le-Grand, E.C.1.

Vacancies.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, may be found at pages 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 50 and 51.

A short summary of *vacant* posts notified in the advertisement columns appears in the *Supplement* at page 47.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

147. Laryngeal Tuberculosis.

E. A. LOOPER and L. V. SCHNEIDER (*Journ. Amer. Med. Assoc.*, October 6th, 1928, p. 1012) have analysed a series of 503 patients with laryngeal tuberculosis treated at the Maryland State Sanatorium from 1923 to 1928. It was found that 15.5 per cent. of the 3,227 cases treated at the sanatorium during that period had laryngeal tuberculosis, and of these 55.6 per cent. were males and 44.4 per cent. females. The onset was most frequent between the ages of 20 and 40. Occupational use of the voice appeared to play no part in the development of the complication. It was generally considered that laryngeal tuberculosis was secondary to a pulmonary infection, and the authors' experience confirmed this view. Lesions of the vocal cords and ventricular bands were most frequent. In the moderately advanced group the sputum contained tubercle bacilli in 92.2 per cent.; in the advanced group 93.4 per cent. had a positive sputum. The authors suggest that prophylaxis should be directed towards ensuring a regular monthly examination of the larynx in all cases of pulmonary tuberculosis. They found that many patients showed well-advanced local lesions without any subjective symptoms. Prophylactic treatment should be adopted towards infected sinuses, diseased teeth, and focal infections in the tonsils. Sanatorium treatment was recommended for patients with laryngeal tuberculosis. If the temperature was above 99.4° the patient was put to bed and complete vocal rest was secured, the patients having to write all requests. The electric cautery (indirect method), applied under local anaesthesia, gave the most favourable results. Of cases so treated 65.5 per cent. with moderate lung involvement improved and healed; 26.5 per cent. with advanced lung involvement improved. There were no bad results, but rather a favourable influence was exercised on the lungs and general condition. Contraindications to the use of the cautery were high temperature, marked asthenia, and high blood pressure.

148. Post-systolic Tension.

A. MOUKHTAR (*Arch. des Mal. du Coeur*, December, 1928, p. 769) has investigated the various forms of arterial hypertension by means of the Uscoff sphygmotonograph. This instrument records the form and amplitude of the arterial pulsations, the systolic and diastolic pressures, and also the post-systolic tension, which is the pressure persisting in the arteries after the conclusion of ventricular systole. If the arteries possess normal elasticity the difference between systolic and post-systolic pressures should not exceed 25 mm. of mercury, while if the arterial walls are unduly rigid the disparity may exceed 60 mm. Other factors influencing post-systolic tension are the output of the heart and the rate of the circulation; it is reduced, for example, when there is incompetence of the aortic valve, but it is increased in cases of arterial hypertension if failure is present. When compensation is re-established by suitable treatment venous return to the heart is facilitated and the post-systolic tension falls. After haemorrhage, or in hypotensive states, this pressure is lowered disproportionately. The author distinguishes two main types of hypertension as revealed by the sphygmotonograph. In the first or nephritic type the vessels are but slightly affected, the post-systolic tension is normal, and the pulse tracing falls away gradually as the pressure is lowered. The second group consists of patients with considerable arterial change but no nephritis; these show excessive amplitude of the arterial pulsations, with a disparity of more than 30 mm. of mercury between systolic and post-systolic tensions. Other varieties described are a mixed renal and arterial type in which the tracings may be difficult to interpret, and a group showing lowered diastolic and post-systolic tensions. The last group consists mainly of patients with diabetes, Graves's disease, and menopausal symptoms.

149. Chronic Cervical Adenopathies.

WHILE chronic cervical adenopathies are easily identified in typical cases, R. NATIVELLE (*Rev. de Med.*, No. 6, 1928, p. 843) remarks that their correct diagnosis is usually a difficult matter, and that they are far too frequently labelled as due to tuberculosis or adenitis, the true condition escaping recognition. They may be confused with such states as lipoma, cyst, fibroma, syphilitic gumma, cold abscess, and actinomycosis, and the various differential points are recorded by Nativelle. He divides adenopathies into primary and secondary forms. The second are the more easily diagnosed, but it is important to ascertain with the greatest care the organ from which the lymphatics run to the affected gland, since the latter may be the only evidence of the initial lesion. Cervical adenitis may be secondary to cancer of the tongue, breast, or stomach; to lingual or pharyngeal tuberculosis; to lingual syphilis; or to a simple dental abscess. The diagnosis of primary adenitis is much more delicate, and the author mentions several types of this condition. These include adenopathies with fistulae and those due to multiple lesions, to tuberculosis, malignancy, actinomycosis, myeloid and lymphoid leukaemia, Hodgkin's disease, and malignant branchioma. Treatment varies essentially with the cause, and Nativelle comments on a few therapeutical indications. In tuberculosis a rigorous hygiene should be instituted, and the administration of arsenic, iodine and iodides, *x* rays, and the methylic antigen of Nègre and Boquet has given good results. Leukaemia and lymphadenoma have been treated with variable success with arsenic, the arsenobenzols, benzol, and thorium, while radiotherapy is the treatment of choice in Hodgkin's disease. Syphilitic adenitis should be treated specifically, and actinomycosis with potassium iodide. In lymphosarcoma and ganglionic cancer only palliative treatment with *x* rays or radium can be instituted.

150. Lumbar Pain due to Uric Acid Tophi.

P. RULLÉ (*Gynecol. et Obstet.*, November, 1928, p. 425) offers some suggestions for the diagnosis and treatment of the lumbar pain which is so frequently a complaint of patients at a gynaecological clinic. He considers that the most frequent direct cause of such pain is the presence of uric acid tophi in the dorsal musculature. Among the cases attending the gynaecological clinic 90 per cent. had tophi only, and 10 per cent. gynaecological lesions only. Tophi were palpated in most of the cases. When present and causing pain they were always palpable. Palpation should be conducted in ventral decubitus. They are hard pellets, often very tender, and situated in the sacral subcutaneous tissue. They are localized at the point of attachment of the dorsal muscles, but sometimes run parallel to the sacro-iliac articulation. The number is indefinite; sometimes they are situated superficially, and sometimes very deep. They are more or less movable, and may be unilateral or bilateral, but the pain is always referred to the side on which they are. All the patients were given treatment for gout, and all lost their pain; only two had previously suffered from recognized gout, but several had undergone gynaecological operations without being relieved of the pain. The medicament employed was lithium bromide, carbonate, or iodide, 0.5 gram, with antipyrine 0.4 gram and extract of belladonna 0.7 gram; this was given twice a day one and a half hours after meals in half a glass of water.

151. The Thyroid Gland and Serum Disease.

A. C. PETITDEMANGE (*Thesis de Nancy*, 1927–28, No. 375) in the first part of his thesis maintains that, as regards the etiology, symptoms, and treatment, serum disease is essentially the same as anaphylaxis; in the second part the various objections to this theory are discussed and refuted. In both conditions the symptoms appear to be due to a vago-sympathetic vasomotor disturbance, and in both there is a presence of foreign albumin in the body fluids which render the system hypersensitive. In the third part of the thesis the author shows that just as the thyroid plays an important part in the phenomena of anaphylaxis, so in serum sickness there is usually a condition of hyperthyroidism, as indicated by an increase in size of the thyroid and characteristic changes in the pulse, blood pressure, and oculo-cardiac reflex.

152. The Incidence of Syphilis in Necropsy Cases.

F. HARBITZ (*Norsk Mag. f. Laegevid.*, October, 1928, p. 18) reviews the findings of the *post-mortem* room during the twenty-eight-year period 1900–27, in which he has been responsible for performing the necropsies at the Rikshospital in Oslo. These numbered 6,529, and among them there were 369, or 5.65 per cent., in which definite syphilitic changes were found. In 303 of these cases, or 4.68 per cent. of the total, syphilis was considered to be the cause of death. Syphilitic changes were detected in the arteries in 202 cases, being the cause of death in 175, and incidental findings in 27 cases. Syphilis of the nervous system was found in 55 cases, being responsible for the deaths of all these patients. It was present in the digestive tract in 28 cases, and was

considered to be responsible for the death of 24; as many as 23 were cases of syphilis of the liver. Syphilis was responsible for the death of 16 of the 18 patients found after death to be suffering from syphilis of the respiratory tract. In all the 24 cases in which syphilis of the skin (scars, gummata, etc.) was found these findings were incidental. There were 13 cases of syphilitic amyloid degeneration, in all of which this condition was the cause of death; there were also 3 fatal cases of severe syphilitic anaemia. Among the 8 cases of syphilis of the bones there was only one in which this disease was the cause of death.

153. Coronary Occlusion in Buerger's Disease.

I. I. LEMANN (*Amer. Journ. Med. Sci.*, December, 1928, p. 807) reports a case of extreme arterio-sclerosis associated with Buerger's disease (thrombo-angiitis obliterans). The patient was aged 59, and Lemann discusses the point whether this condition had any relation to the thrombo-angiitis which had to be treated by successive amputations. He recalls the fact that in two of Buerger's necropsies—on patients aged 21 and 35—there was precocious arterio-sclerosis, and he concludes that in thrombo-angiitis obliterans the pathological process is probably not limited to the vessels of the extremities. In Lemann's case the aorta was found to be very much thickened, with numerous large calcareous elevated plaques. The coronary arteries were much sclerosed, and there was a calcareous patch on one of the cusps of the aortic valve. The opening of the left coronary artery was almost occluded by calcareous deposits, and there was complete occlusion of the branches of the right coronary artery by a similar process of calcification. The cut surfaces of the heart wall showed a very great preponderance of fibrous tissue; the coronary artery, however, was free from the lesion of thrombo-angiitis obliterans. Lemann notes that coronary occlusion has been found in four out of five necropsies on patients with Buerger's disease.

Surgery.

154. Early Diagnosis of Acute Osteomyelitis.

M. NAKATA (*Deut. Zeit. f. Chir.*, December, 1928, p. 132) describes a simple method of demonstrating fat droplets in the blood. From the cubital vein 0.5 to 1 c.cm. of blood is removed and immediately mixed with an equal volume of an alcoholic solution of Sudan III in a small chemically clean Petri dish. When the mixture has stood for a few minutes it is examined microscopically under a low-power lens or with a magnifying glass in the dish. Applying this procedure to the diagnosis of inflammatory bone conditions the following results were obtained. Of 15 cases of acute osteomyelitis 87 per cent. were positive; in chronic osteomyelitis 20 per cent.; immediately after sequestrotomy and scraping of the medullary cavity 100 per cent.; and in experimental osteomyelitis in animals (damaging the bone marrow electrically in rabbits and then injecting a suspension of bacteria into a vein in the ear) fat droplets were demonstrable in almost every case. In control tests carried out by Matsubayashi, in acute and chronic inflammatory conditions of the soft parts (furunculosis, carbuncles, phlegmons, and abscesses), fat droplets were invariably absent from the blood; similarly in acute inflammations of joints and in tuberculosis of bones and joints. Fat droplets were comparatively frequently found in the blood of women during lactation. Nakata remarks that since the fat droplets in acute osteomyelitis are swept into the blood intermittently, and disappear from the circulation again in ten minutes or less, the examination should be repeated several times if necessary. As the pathological condition becomes more chronic the test tends to become negative; also, during early infancy when the bone marrow contains little or no fat, it may not be possible to demonstrate fat droplets in the blood in acute osteomyelitis. With these reservations Nakata considers that though a negative result does not entirely exclude an acute osteomyelitis, a positive droplet test is strong evidence in favour of acute osteomyelitis. On account of its simplicity and accuracy the test should prove a valuable aid in the early diagnosis of this condition.

155. Congenital Pseudarthrosis of the Tibia.

R. B. WADE (*Journ. Coll. Surg. Australasia*, November, 1928, p. 181), from observations on ten patients, discusses the so-called congenital pseudarthrosis of the tibia; this condition is not merely a fracture which fails to unite, but one which is preceded by pathological changes in the bone in the lower middle fourth of the tibia and occasionally in the fibula also. Cases are of the following types: those seen before fracture showing bone changes at the site of subsequent fracture, and those seen after fracture in which either union has occurred of a soft yielding nature for some years, or in which a pseudarthrosis has supervened with no attempt at bone regeneration. The fracture may be present at birth or may occur later. Radiographically there may be found at birth areas of porosis crossed by a few bone trabeculae, causing swelling of the bone and usually some forward bowing. The x-ray appearance is identical with that of osteitis fibrosa cystica occurring at the site of the curve at the anterior edge of the tibia; an area of rarefied bone commences at the periosteum and extends partly or completely through the depth of the tibia, ranging from an inch to an inch and a half in length. Whether a pseudarthrosis or slow union supervenes after fracture, there is always pronounced shortening of the leg and foot, development being slower than on the other side. For some obscure reason there appears to be a deficient osteogenetic power at this part of the tibia. Treatment with a sliding bone-graft from the same side gave the best results but was disappointing, the bone yielding at first; in three cases firm union resulted eventually, though with some bending and deformity. K. INGLIS (ibid., p. 194), from an examination of specimens from three of the above cases and from a study of the literature, discusses the pathology of the condition. It is suggested that complete absence of the tibia or of its lower part, congenital fracture with shortening, pseudarthrosis without shortening, and simple bends may all be due to malformation, representing different grades of one pathological process, the difference being one of degree and not of kind. The author thinks that the tendency to such malformation is transmitted by the germ plasm.

156. A Rare Form of Intestinal Obstruction.

ACCORDING to WODARZ (*Zentralbl. f. Chir.*, December 8th, 1928, p. 3082) intestinal obstruction due to tumour of the genital organs is very unusual. The majority of such cases are caused by the adhesion of coils of intestine to the inflamed surface of tumours, or to kinking or obliteration of the lumen of the bowel. He reports an infrequent type of case in a poorly nourished woman, aged 72, who was admitted suffering from faecal vomiting; she had had acute intestinal obstruction for a week. For ten years she had been conscious of the existence of a tumour as large as an adult head in the left hypogastric region. A band extending from the anterior surface of this tumour to the uterus could be felt; it was tensely elastic, nodular, slightly mobile, and tender on pressure. In the right hypogastric region peristaltic contractions were present. The abdominal wall was not very tense and could be palpated easily. At a laparotomy it was found that there was on the surface of a multilocular intraligamentous ovarian cyst a scarred, thickened, strangulating hernial ring, measuring four-fifths of an inch in diameter. Within the hernial sac which lay inside the cyst was a mass of strangulated small intestine as large as a man's fist. Wodarz concludes that the only possible explanation of this condition is that a daughter cyst had ruptured and that the coil of small intestine had been forced into the cavity thus formed.

157. Pulmonary Gangrene.

BAUMGARTNER (*Bull. Soc. Nat. de Chir.*, December 1st, 1928, p. 1270) reports two cases of massive gangrene of the lung successfully treated by excision of the necrotic focus. The author considers that early operation in these cases is contra-indicated, and that surgery is indicated only after adequate medical treatment has been employed without benefit. To ensure success in these cases it is important to operate in stages, at intervals of a few days. General anaesthesia is said to be unnecessary, and in the later operations the author has dispensed with local anaesthesia and relies on morphine. In the first stage he makes a free opening in the thoracic wall, excising a portion of rib, but does not open the pleura. In the second stage he opens the pleura (guided by radiograms) and removes the necrotic mass. In the second operation the lung is fixed to the parietes by suture, and so far the author has had no trouble with haemorrhage. Baumgartner thinks that in some cases where haemorrhage is especially to be feared it might be useful to perform preliminary phrenicectomy. The best time to operate—always a difficult question to settle—should be decided by consultation between the physician and the surgeon.

158. Adenoma of the Suprarenal Cortex.

J. B. HICKS (*New England Journ. Med.*, December 6th, 1928, p. 1140) reports a case of adenoma of the suprarenal cortex occurring in a woman, aged 48, and discusses the incidence and treatment of this rather rare condition. The most prominent symptoms were irregular menstruation, frequency of urination, dragging pain in the abdomen, a general yellowish-brown pigmentation of the skin, and the development of a tumour; some urinary haemorrhage occurred. At this at first was thought to be vaginal. A diagnosis was made of splenomegaly, but a pyelogram of the left kidney showed displacement of this organ downwards, with compression of the upper calyx, and the presence of a hypernephroma was therefore suspected. The growth was removed and

patient recovered completely. Microscopical examination of the tumour showed that it was a typical cortical adenoma of the suprarenal gland. Discussing this condition, the author comments on the absence of the usual symptom of virilism in this patient. All established instances of such tumours discovered clinically have occurred in children or in adult females; adenomata of the suprarenal cortex have been detected in adult males at necropsies, in spite of the absence of symptoms during life. Hicks adds that a surgical operation should always be performed in the case of a renal tumour without metastasis, since it may prove to be a non-malignant and removable suprarenal adenoma.

159. Cause of Death in High Obstruction.

H. S. F. COOPER (*Arch. of Surg.*, December, 1928, p. 918) discusses the fact that whereas a simple obstruction of the large intestine is compatible with life for a long time, a similar condition affecting the small intestine is rapidly fatal. While offering no complete explanation of this difference, he remarks that in high obstruction two different processes are involved—a profound disturbance in the acid base mechanism resulting in alkalosis and dehydration, and a definite toxaemia. In simple obstruction the former is the more prominent, but in closed loops and strangulation the toxaemia is very marked, owing possibly to a toxin in the lumen of the obstructed gut reaching the blood stream. Cooper suggests that there may be some mysterious connexion between the toxaemia of high obstruction, acute pancreatitis, bilateral suprarenalectomy, and anaphylaxis. The mental condition of the patient is often misleading, since he is usually alert and unaware of the seriousness of his condition. The cheeks are often sunken and the eyes bright; in later stages the patient presents the typical Hippocratic facies. His extremities are cold and clammy, and his lips and nail-beds are often cyanotic; twitchings of the hands and feet, and beads of perspiration, are other symptoms. Usually a deep coma intervenes before death. Vomiting, at first of gastric and duodenal contents and later of a faecal character, is a constant symptom. The temperature is normal or subnormal, the pulse weak and rapid, respiration shallow, and blood pressure low. Patients suffering from uncomplicated obstruction of the small intestine rarely survive more than six or eight days unless early surgical intervention takes place.

160. Surgical Treatment of Gall-stones Complicated by Jaundice.

H. HARTMANN (*Bull. et Mem. Soc. Nat. de Chir.*, December, 1928, p. 1430) emphasizes the risk of an operation for gall-stones when the patient is suffering from jaundice, and suggests that where there is no urgency the symptoms should be relieved by other treatment, such as the insertion of a duodenal tube. Out of a series of 34 cases collected by *Bengolea and Suarez* 21 patients were operated on at a later date and 13 had no operation. In most instances the tube extracted bile from the duodenum, but in seven there was an appreciable quantity of bile. The presence of bile in the duodenum was not constant, and it was necessary to reinsert the tube frequently in order to make sure that the duodenum was completely empty of it. In severe cases, when the jaundice is of long standing, the tube is inserted for twelve hours, while duodenal feeding, consisting of alkalis, the juice of raisins, and a concentrated solution of glucose and milk, is administered. At the same time insulin and biliary disinfectants are given, and in many cases blood transfusion is performed, after which the patient is in a better condition to undergo an operation. In addition to the duodenal drainage, the patient is fed on mashed potatoes, honey, sweets, and fruit. By this means an appreciable improvement in the general condition is obtained and also a gain in weight. In less severe cases the tube is kept in for five hours a day, it being advantageous to stimulate the duodenal secretion by concentrated solutions of magnesium sulphate.

161. Gynaecomastia.

G. MARAÑON (*La Med. Ibera*, December 22nd, 1928, p. 659) states that gynaecomastia, or abnormal development of the breast in the male sex, may be met with under the following conditions. (1) In the newborn there may be a mammary hypertrophy and sometimes an actual mastitis, so that the term "foetal gynaecomastia" is applicable. This is only a transient phenomenon. (2) A certain number of boys also show a transient gynaecomastia at puberty on one or both sides. In rare instances there may be a secretion of serous or milky fluid. The psychical state and sexual instincts in such cases appear to be normal. (3) Gynaecomastia may be a permanent condition and form a symptom of male pseudohermaphroditism. (4) A fair number of cases of late gynaecomastia have been described occurring in youth or maturity in males who had hitherto been normal. In such cases the development of the breast has generally been due to physiological stimulation—namely, repeated suction. In some cases there has been not only an anatomical hypertrophy, but also a permanent secretion of milk sufficient to feed an infant. (5) Mammary hypertrophy may sometimes develop after castration, with other signs of eunuchism. (6) Gynaecomastia may also occur apart from castration in association with other spontaneous endocrine changes, such as Fröhlich's syndrome, acromegaly, or hyperthyroidism.

162. Metacarpo-phalangeal Ganglion.

M. BUFALINI (*La Chir. degli Organi di Movimento*, October, 1928, p. 23) discusses a type of ganglion which appears on the palmar aspect at the junction of the metacarpus and the phalanges. It may arise as a primary or secondary affection, and is commoner in the female than the male. Slight continued traumatism can sometimes be incriminated as a cause, and the author discusses more hypothetical reasons for its appearance. As in the case of other ganglia, there may be a connexion with the synovial membrane or with the tendon sheath. Sometimes this form of ganglion is painful from the start, but at other times causes no symptoms; as a rule it is quite small, and can be fairly easily crushed. When due to tenosynovitis it is useless to deal with the ganglion unless the tenosynovitis is cured. Bufalini adds that study of the anatomical distribution of the fascia round these joints throws some light on the reason why ganglia may occur at this point, for the fascia is relatively weaker at the metacarpo-phalangeal junction.

Therapeutics.

163. Treatment of Functional Heart Disease.

F. J. HIRSCHBOECK (*Journ. Amer. Med. Assoc.*, December 15th, 1928, p. 1852) separates from the group of functional disorders of the heart those non-cardiac diseases which in their early stages produce cardiac symptoms. Among the conditions most commonly causing such symptoms are disturbances of the endocrine organs, anaemia, early hypertension, and diseases of the lungs, kidney, and liver. There are two main groups of functional heart disease: neurocirculatory asthenia, and cardiac neurosis due to psychogenic and emotional causes. In the former psychotherapy and hygienic teaching are of the greatest importance. The patient should be told that although he has a normal cardiac mechanism he has a limited reserve, that the condition is not progressive, and that average capacity can be restored. Efforts should be made to ward off infections which invariably aggravate the symptoms. Graduated recreative exercise such as golf, nine hours' rest at night, and moderation in everything should also be recommended. Bromides are often helpful, and an attempt should be made to improve the general condition of the patient by nutritious diet and physical therapy such as ultra-violet light. The group of psychogenic and emotional cardiac neuroses depend essentially upon psycho-analysis for their successful treatment. Many patients are quickly restored to mental and emotional comfort when their fears of cardiac disease are shown to be groundless, and when the relationship between symptoms and psychic distress is explained. Such patients, like those of the first group, also benefit from adequate rest and mental diversion, but attempts at building up physique and endurance are not so essential. Diet is chiefly of importance in the avoidance of gastro-intestinal disturbances. Physical therapy, exercise, and massage are useful only to patients who can give enthusiastic co-operation.

164. Treatment of Vasomotor Rhinitis with Tuberculin.

N. DE FINE BUNKEFLOD (*Ugeskrift for Laeger*, November 22nd, 1928, p. 1091) was induced by the success following the treatment of bronchial asthma with tuberculin to try this remedy in an allied complaint — vasomotor rhinitis. He records the case of a man, aged 29, who had been subject to violent attacks of vasomotor rhinitis since the age of 10. His mother and aunt suffered from bronchial asthma, and he himself had suffered twice from Besnier's prurigo. The violent attacks of vasomotor rhinitis occurred in the hay fever season, or soon after his bed had been made. They were of almost daily occurrence, and they could be aborted by the taking of 0.5 mg. of atropine by the mouth about 15 minutes before an attack was due. Cutaneous tests with cat's hairs, goose feathers, and certain grasses provoked large vesicles. Pirquet's reaction was positive. A course of ten injections of Koch's old tuberculin, at intervals of a week, was given, the first dose being 1/10,000 c.cm. There was a violent local reaction, and the temperature rose to 102°. The same amount a week later provoked an equally violent reaction. The dosage for the following six injections was therefore reduced to 1/100,000 c.cm., but that of the ninth

and tenth injections was increased to 1/50,000 c.cm., since the previous injections had provoked only a slight rise of temperature (100°). The attacks of vasomotor rhinitis ceased during this treatment, and had not recurred six months later. The patient could now lie in a haystack with impunity and touch without discomfort the mucous membrane of his nose with the same grass to which he had been shown to be sensitive.

165. Treatment of Hay Fever.

M. A. RAMIREZ (*Amer. Journ. Med. Sci.*, December, 1928, p. 856) reports statistically on 425 cases of hay fever due to irritation by pollen from grasses or ragweed. His therapeutical conclusions are as follows. It is important to give a large amount of pollen before the onset of the season, and to continue treatment throughout it. Local desensitization increases the relief, and the combination of autogenous vaccines with pollen treatment before and during the season is helpful. The Kromayer lamp benefited some patients but not others; it seemed to reduce the local irritability of the nasal mucosa and was, as a rule, more helpful in non-specific vasomotor rhinitis than in specific pollen cases. Autogenous vaccine treatment without the use of pollen in specific cases did not result in benefit, and local pollen treatments without pollen injections were also of no value. The greater benefits obtained by the use of several pollens is attributed to the fact that in these cases a much larger dose of total protein was injected. The best results were obtained in the case of patients treated about three months before the expected date of pollination. They received two weeks' intensive treatment, the dose of pollen being rapidly increased, and injections were continued up to the pollen season, reaching as high a dose as possible. Subsequently injections were continued twice a week during the entire season; injections of autogenous vaccines, prepared from the nose, were also given, and local treatment was applied to the nose and eyes. It was found that mild symptoms in fairly well immunized patients could be controlled by ephedrine, particularly if combined with small doses of codeine and atropine; in untreated cases, however, ephedrine was uncertain in its action.

166. Autohaemotherapy in Skin Diseases and Infections.

A. RISI (*Studium*, November 20th, 1928, p. 479) gives an account of his treatment of a series of acute cases by means of autohaemotherapy. With an ordinary syringe 4 to 6 c.cm. of blood is removed from the patient's median basilic or cephalic vein and immediately injected into the gluteal region; the procedure is repeated every two days. The author has had no case of shock, febrile reaction, or pain at the site of injection. He reports 53 cases illustrating the very diverse ailments which he treated in this manner; these include measles, whooping-cough, erysipelas, influenza, typhoid fever, and various acute lung conditions. Between 70 and 80 per cent. cures are claimed. The author gives a detailed account of a patient suffering from a chronic skin disease. Although the eruption conformed largely to the classical description of acanthosis, it was red, and had some of the characteristics of a lichen; Risi therefore named it *Acanthosis ruber lichenizzante*. Cure followed administration to the patient of thirty injections of his own blood, 10 c.cm. being given on alternate days. Three chronic cases of moist eczema were effectively treated in the same way. The author discusses the interpretation of these results. The dosage for children was 1 c.cm. of blood for each year of age, but never less than 6 c.cm. for those under 7 years.

167. A Combined Treatment of Pulmonary Tuberculosis.

G. BRECCIA (*Il Policlinico*, Sez. Prat., December 10th, 1928, p. 2438), reviewing the changes that have occurred during the last twenty years in the treatment of pulmonary tuberculosis, concludes that the pathological condition rather than the exciting cause should be deal with, and attention be devoted to the metabolism, chemiotherapeusis, desensitization, and antitoxin formation. He defines dysplasic, dystrophic, dystonic, and toxic effects, and suggests a line of treatment based on combating these conditions severally and collectively. He employs organic extracts of liver, spleen, and bone medulla, certain lipoids, calcium, camphor, and ether. The various methods of giving these substances and the results to be expected from their administration are considered in detail. For children he uses a solution of 5 c.cm. of ether in 7 c.cm. of olive oil, and gives injections of 1 c.cm. for three days, 1.5 c.cm. for two days, and 2 c.cm. for six days, followed by a pause of three to five days. The series is repeated indefinitely. The solution for adults contains 10 eg. of lecithin and of camphor, and 1/10 c.cm. of pure ether (10 per cent. in volume); 1 mg. of strychnine is added sometimes. From 1 to 4 c.cm. of this solution is given. The difficulty of the treatment is apparently to find a hepato-spleno-medullary extract of reliable action.

Radiology.

163. Synchronization in Accurate Diagnosis of Chest Diseases.

F. M. MCPHEDRAN and C. N. WEYL (*Radiology*, December, 1928, p. 458) explain that synchronization as applied to chest radiography means making exposures at selected phases of the cardiac cycle. The pulse wave is employed as the source of excitation. In the technique the authors use a cannula, applied over the carotid artery, a tambour, a tiny mirror, an intense beam of light, a photo-electric cell, specially designed amplifying vacuum tubes, an *x*-ray switch, and an *x*-ray exposure timer. Pairs of films that are synchronized so as to be exposed in the same phase of the cardiac cycle are truly stereoscopic. By synchronization with late diastole, films may be made at a time when cardiac movement is at a minimum. This is the most satisfactory phase in which to secure good lung detail. That vibration is set up in the lung by the pulse wave is evident from (1) the finer detail shown in films made from the same individual on the same day when the pulse is slow than when it is fast; (2) the greater peripheral detail in exposures made in late diastole than in systole; and (3) the marked pulmonary detail in an emphysematous lung, where elasticity has been lost. The authors claim that synchronization permits of the best obtainable recording of normal structures arborizing from the hilum; renders visible slight differences in general or local prominence of the normal markings; and distinguishes them from the irregularly disposed, asymmetrical, infiltrative processes between the normal structures. The generalized prominence of venous trunks may form a very delicate test of cardiac failure. The exposures were a *twentieth* or a *twenty-fifth* of a second at the distance of fifty inches.

169. Effect of X Rays on the Reticulo-endothelial System.

IT has been suggested that the effect of *x* rays on carcinomata is produced through the reticulo-endothelial cells, and, as Pfeiffer and others have shown that one of the functions of these cells is the storage of electro-negative colloids, H. ZACHERL (*Wein. klin. Woch.*, November 22nd, 1928, p. 1613) has performed a series of preliminary experiments to ascertain the effects of *x* rays on rabbits from this point of view, by estimating the rate of storage of ferrum saccharatum oxydatum injected intravenously six hours after the rabbit had been irradiated. The total iron in the blood was estimated four minutes and one hour after the injection, and the following conclusions were reached. The storage capacity depends on the dose of *x* rays applied. After a large general dose of the rays the storage of ferrum saccharatum was diminished in comparison with the normal control. After a small general dose the iron content of the blood was diminished; this is ascribed to increased storage capacity of the reticulo-endothelial cells due to stimulation by the small doses of *x* rays. It was also observed that a leucopenia occurred in each animal after these small doses, and that no change in the protein content of the serum could be demonstrated which might account for the disappearance of part of the iron from the circulation.

170. The Scope of Heliotherapy.

P. DUHEM (*Journ. de Méd. et de Chir. Prat.*, November 10th, 1928, p. 770) deprecates the injudicious employment of radiotherapeutic treatment by the inexperienced; in children the cell protoplasm is particularly sensitive to the physico-chemical reactions thus produced. Feeble doses stimulate protoplasm, while more powerful doses may be rapidly fatal. The ultra-violet rays produce a rapid increase in the haemoglobin index, which remains above normal for a long period; the differential blood count varies simultaneously, while the calcium and phosphorus percentages are much increased, as is also the alkaline reserve. Blood regeneration is much more rapid under this treatment, which appears to replace vitamins A and D. Ultra-violet rays act energetically on the sympathetic nervous system, especially in relation to the skin and endocrine glands; this probably explains the beneficent action in asthma. The rays affect also the central nervous system, improving muscular tone, either by means of the vago-sympathetic system, or possibly by their effect on phosphorus metabolism. The antirachitic property of irradiated foods is retained even after exposure to air or after boiling, but prolonged ultra-violet irradiation destroys the antirachitic properties of cod-liver oil and of irradiated vegetable oils. Irradiated ergosterol is five hundred times more active than irradiated cholesterol, and is very valuable in tetany and spasmophilia, but direct actinotherapy has a more persistent action, and should always be used in refractory encephalopathic conditions. Some authors have

recorded successes in the treatment of tuberculosis with irradiated ergosterol. Duhem believes that these irradiated substances will largely replace artificial actinotherapy, though they will not supplant it entirely.

Obstetrics and Gynaecology.

171. Prophylaxis and Treatment of Eclampsia.

J. L. WODON (*Bruxelles-Médical*, December, 1928, p. 171) suggests that albuminuria must not be considered the most important or constant sign of approaching eclampsia, since convulsions may occur with no albumin present. He believes that a rise in the blood pressure to about 140 mm. of mercury precedes both eclampsia and albuminuria. When this pressure is present he restricts the diet to milk and water for a week, giving two or three litres in the twenty-four hours; the alimentary tract is cleared by purgation and lavage, and in some cases he prescribes also Vichy water or sodium bicarbonate. According to the improvement shown, the diet may be modified to include vegetables. With this regime Wodon asserts that, although the albuminuria may persist, the blood pressure is lowered and the acidosis disappears in a week. In eclampsia he advocates the treatment of each individual symptom according to its intensity. Isolation, quiet, and a dim light are essential, and, to avoid unnecessary sensory stimulation, the patient should be handled with extreme care. Convulsions are treated by a repeated hourly intramuscular injection of 10 c.cm. of a 50 per cent. solution of magnesium sulphate, and in cases where this may not be tolerated it is well to have in readiness for intravenous injection 10 c.cm. of a 10 per cent. solution of calcium chloride. Morphine may be used as an alternative to magnesium sulphate. For a raised blood pressure he relies on venesection; the acidosis he treats with bicarbonate drinks and lavage; and for anuria he believes in the administration of 300 to 500 c.cm. of hypertonic glucose solution intravenously, following venesection. He adds that delivery should be aided by forceps, with ether anaesthesia; Caesarean section should only be performed when other obstetrical complications are present. During convalescence a diet which throws little strain on the kidneys and liver should be given, the function of the former being tested periodically by the phenolsulphonephthalein method.

172. Biological Disinfection of the Vagina.

A. SMORODINZEW and G. TUMANOW (*Zentralbl. f. Gynäk.*, November 17th, 1928, p. 2978) report a method of treating the vagina with a pure culture of *B. döderleini*, which gave good results. Suspensions of this bacillus are said to have a powerful effect on the vaginal bacterial content; in a sugary medium it forms lactic acid in strong concentration which inhibits other less acid-fast organisms; it acts specially well on monosaccharides. The procedure is as follows. Fresh ox liver is boiled with double the amount of water and 1 per cent. peptone and 0.5 per cent. salt, and filtered. A 2 to 4 per cent. solution of glucose is added to the filtrate, which is then sterilized. Some drops of a polyvalent culture of Döderlein's bacillus are dropped on a tampon soaked in this solution; this is introduced into the vagina, after douching with normal saline, and left for twenty-four to thirty-six hours. The bacterial content of the vagina was examined before, during, and after treatment, and the *p*H estimated. Acidity increased in the first twelve hours and then remained stationary for twenty-four hours; when all signs and symptoms had gone, treatment was discontinued for seven to thirty days; then, if necessary, it was repeated and continued for two to three weeks. The authors have treated twenty-five cases of chronic vaginitis and leucorrhoea, and in thirteen of these there was, in addition, some cervical change, such as erosion, endocervicitis, or metritis colli, pus-forming organisms being present in large numbers. Improvement was seen after two to four applications in the first twelve cases; the discharge lessened, pus-forming organisms were replaced by Döderlein's bacillus, phagocytosis was increased in some, and desquamation followed. A *p*H of 6.1 to 6.8 before treatment is particularly recommended in local inflammatory conditions of the lower genital tract, and also as a prophylactic procedure in midwifery and before operations.

173. Gynaecological Uses of Massage.

V. LIEBERMANN (*Med. Klinik*, November 9th, 1928, p. 1749) remarks that a number of gynaecological disorders involve not only the pelvic organs, but also the pelvic connective tissue and the muscles and nerves of the walls of the pelvis, and that tenderness of the lumbar and gluteal muscles and tendons, especially near their attachments to the sacrum, is generally also present. The various symptoms commonly grouped together as backache often include pains extending from the lowest ribs down into the thighs or round into the lateral parts of the abdomen. It can frequently be demonstrated that pressure at certain points on the inner wall of the pelvis corresponding with the intrapelvic course of the obturator nerve and the branches of the sacral plexus will produce pain with a similar distribution. Likewise, pelvic adhesions and displacements may also cause such pains by exerting pressure on these nerves. These conditions cannot be cured or relieved by treating only the pelvic organs; v. Liebermann has, however, obtained satisfactory results in a number of cases by supplementing the more usual forms of treatment by a type of gynaecological massage originated by Thure Brandt some fifty years ago and since neglected. If there is any evidence of infection, or if there has been a miscarriage within one year previously, this form of treatment must be avoided for fear of lighting up the infective process. The technique for stretching adhesions is as follows. One hand presses down gently but with gradually increasing firmness through the abdominal wall on to the band of adhesions, which is supported by a finger introduced into the vagina and kept practically stationary. The adhesions are gradually stretched, mainly by the manipulations of the abdominal hand; after the treatment has been repeated several times the normal mobility of the pelvic organs is frequently re-stored, and replacement of the displaced organs becomes possible. Considerable improvement has even been produced in cases of prolapse by this means. A similar manœuvre will also often benefit old endometritis and perimetritis by inducing hyperaemia. Massage of the fascia, muscles, and nerves of the pelvic walls, though it may be very painful, has also been found valuable in cases with neuralgic pains. When there is tenderness of the gluteal and sacral regions, vigorous massage here may be required in addition.

174. Menstruation and Pulmonary Tuberculosis.

A. BEEKMAN (*Zeit. f. Tuberk.*, November, 1928, p. 273), who records four illustrative cases in patients aged from 19 to 39, states that he found premenstrual rise of temperature in 76 per cent. of the cases examined in his sanatorium. While a rise up to 99.6° is not a proof of the activity of the disease, a higher temperature in the absence of intercurrent disease indicates that the process in the lung has not yet been checked. A considerable rise of temperature at the end of the premenstrual period should be regarded as a sign of activity. Cases with febrile or well-marked subfebrile temperature do not present a premenstrual rise. This is an unfavourable proguostic sign indicating the presence of a decidedly active and progressive process. Beekman remarks that the course of the fall of temperature after the onset of menstruation is of considerable clinical interest. Delay in the fall indicates that the pulmonary process is still active, and the duration of the delay in the fall of temperature can always be regarded as a measure of the activity of the disease at the time. High intramenstrual or postmenstrual fever only occurs in progressive disease, and is of unfavourable prognosis. Two factors may be regarded as responsible for these various types of temperature, the first being the morbid process itself with its toxic action, and the second the influence of endocrine processes (corpus luteum and thyroid). The occurrence of intramenstrual and postmenstrual fever is explained by changes in the process of immunity which occur during menstruation.

Pathology.

175. Effect of Drugs upon Stomach Movements.

As a sequel to the investigation of the effect of stimuli on the nerves of the stomach with the organ *in situ*, E. D. M'CREA and A. D. MACDONALD (*Quart. Journ. Exper. Physiol.*, December 12th, 1928, p. 161) were led to study under similar conditions the action of drugs upon its movements. After tying the pylorus the endogastric pressure was recorded by means of a catheter through the oesophagus connected to a water manometer. The animal's general condition was controlled by a simultaneous record of blood pressure, thus helping to distinguish between responses due to a direct effect on the stomach and those due to circulatory disturbance. The drugs were given intravenously, and nerve stimulations were interpolated between the injections for comparison. Thirty cats and six dogs under ether or chloralose anaesthesia were employed, and decerebrate and spinal cats were also used in order to eliminate the complicating factor of an anaesthetic. Drugs stimulating or paralyzing autonomic nerves were chiefly examined, but the action of general nerve stimulants such as strychnine, and drugs such as histamine and posterior pituitary lobe extracts, were also investigated. Adrenaline was found

almost invariably to cause a fall of endogastric pressure with diminution or cessation of rhythmical movement, varying in magnitude and duration according to the dose given. Ephedrine in non-toxic doses and nicotine were found to act similarly to adrenaline, as also was ergotamine in doses of not more than 2 mg., but it was noted that within a few minutes the inhibitory action of adrenaline might be diminished or absent, while the pressor effect on the circulation was enhanced. Pilocarpine, physostigmine, and acetylcholine in suitable doses produced a similar effect to that following stimulation of the vagus. Atropine in 0.1 to 0.15 mg. doses was found to reduce endogastric pressure and arrest movements of the stomach musculature, while strychnine had no marked effect either on movements or pressure. Of drugs believed to act directly on plain muscle, histamine brought about a transitory rise of pressure and augmentation of movements, while extracts of the posterior pituitary lobe caused a fall of pressure and cessation of movement. These experiments with drugs confirmed the authors' conclusions from stimulation of the stomach nerves and render untenable the theory of the vagus being excitor and the splanchnic nerve inhibitor, both appearing to be capable of an augmentor or inhibitory action according to the state of "tonus" at the time. A rise of tone is generally associated with increased movements and a fall with cessation, but this is not invariable, and under certain conditions movements and tonus may vary inversely instead of directly.

176. Complement in Health and Disease.

THE attention of L. G. HADJOPOULOS and R. BURBANK (*Journ. Lab. and Clin. Med.*, November, 1928, p. 131) was drawn to the significance of complement by work on immune serums and therapeutic and protective vaccines. It was noted that, in the treatment of chronic infective arthritis, patients with a high complement titre gave a favourable response; that in long-standing debilitating diseases the titre was very low; and that in cases of subacute or chronic septicaemia, when death was approaching, the titre was markedly subnormal, if not entirely absent. The authors report a study of complement in connexion with the determination of the average combined haemolytic titre in healthy subjects under normal circumstances in contrast to some common infectious diseases, and also in regard to the nature and origin of complement. Complement is defined as that particular proteolytic property of active serums which reacts only in the presence of a specific antibody, bacteriolysin, cytolysin, or proteolysin. The average complementary titre in 2,000 apparently normal subjects was found to be represented by 0.04 c.cm. of active serum. During an infectious disease the complement shows considerable variations, which have prognostic significance. With the onset of disease the complement steadily rises. This stage passes rather abruptly into the negative phase, the serological shock period, with an abnormal fall in complement. This fall is probably due to increased complement destruction or absorption from the sudden flooding of the blood with proteolytic by-products of anti-complementary properties. During convalescence and the establishment of recovery the ratio of this production and destruction is reversed, and in the course of a week the titre gradually mounts to normal and remains there. Deviation from this regular course occurs in oncoming complications, relapse or recrudescence, but a gradually mounting complement is a favourable sign. In fatal cases the titre either falls very low or runs a subnormal course. Owing to the close relationship between the metabolic and complement studies in acute infectious diseases, the authors consider complement as a katabolic product of which the system makes an economic use.

177. Effect of Humidity and Temperature on the Resistance to Tuberculosis.

ANNA M. BAETJER and LINDA B. LANGE (*Amer. Journ. Hygiene*, November, 1928, p. 935) have carried out an experimental study on guinea-pigs to determine whether exposure to a hot moist atmosphere diminishes their resistance to experimental tuberculosis. There is evidence that in New England the deaths from tuberculosis are considerably higher among operatives in cotton factories than among those engaged in other industries; as it is in the spinning-rooms that the death rate is highest, the view has been put forward that it is the atmospheric conditions that are chiefly responsible for the increased mortality. Two groups of comparable guinea-pigs were chosen; one group was placed in an atmosphere having a temperature of about 80° F. and a relative humidity of about 79 per cent., the other group was placed in the ordinary animal room, which had a temperature of about 69° F. and a relative humidity of about 45 per cent. After the animals had been kept under these conditions for six weeks they were infected by inhalation with a moderately virulent strain of a human tubercle bacillus. During the following twenty-one weeks 6 of the normal group died out of a total of 36, and 4 of the experimental group. The surviving animals were killed; 11 of the normal group showed tuberculous lesions, and 14 of the experimental group. There was no indication either in the mortality or necropsy findings that there was any difference between the two groups. The experiment was repeated on two batches of 27 guinea-pigs, which this time were infected intraperitoneally, using a dose of 10 million organisms per 100 grams of body weight. All the animals developed tuberculosis. During the eleven weeks following inoculation 14 died in the normal and 15 in the experimental group. The authors conclude that there is no evidence to suggest that the resistance of the guinea-pig to experimental tuberculosis is diminished by exposure to a hot moist atmosphere. They point out, however, that these results are not necessarily applicable to man, because (1) the guinea-pig is originally a tropical animal; (2) the animals took no forced exercise; (3) the animals were not exposed to sudden changes of temperature morning and night.

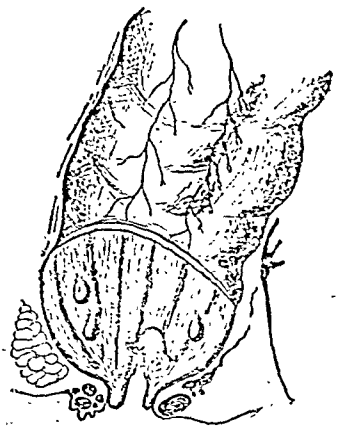
178. The Carbohydrate Metabolism of Certain Pathological Overgrowths.

H. G. CRABTREE (*Biochem. Journ.*, vol. xxii, No. 5, 1928, p. 1289), using Warburg's technique, has studied the carbohydrate metabolism of lesions caused by certain intracellular viruses. According to Warburg the characteristic feature of the cells of malignant tissues is their power of breaking down carbohydrate to lactic acid, even under aerobic conditions. The ratio $\frac{\text{aerobic glycolysis}}{\text{respiration}}$ was found by him to be about 3 for tumour tissue and small or zero for normal tissue. The author cut very small pieces of tissue from the lesions studied, suspended them in Ringer's solution containing $NaHCO_3$ and 0.2 per cent. glucose, and estimated (1) the c.mm. of oxygen used per milligram of tissue per hour; (2) the c.mm. of CO_2 evolved by lactic acid formation in oxygen per milligram of tissue per hour; and (3) the c.mm. of CO_2 evolved by lactic acid formation in nitrogen per milligram of tissue per hour. These estimations afford an indication of the metabolic activity of the tissue, and of the amount of glycolysis occurring under aerobic and anaerobic conditions. The results obtained were as follows. In lesions characterized by epithelial hyperplasia, such as those of fowl-pox in pigeons, vaccinia in young chickens, and human warts, an active metabolism was found corresponding to that in malignant tissues. On the other hand, in lesions characterized by little or no cellular hyperplasia, such as the brain of the rabid guinea-pig, the metabolism was similar to that of normal cells. Great variability was found in the respiratory values of the Rous sarcoma; but evidence was obtained that, after injection of chickens with a cell-free filtrate, the typical Rous cells assumed on their first appearance the high metabolic activity characteristic of the fully grown tumour. The general conclusion drawn by the author is that the magnitude and relationships of the respiratory and glycolytic processes found by Warburg to be characteristic of malignant tissues are not specific for malignant tissues, but are a common feature of pathological overgrowths.

179. Flagellar and Somatic Agglutination.

J. B. NELSON (*Journ. Exper. Med.*, December, 1928, p. 811) has worked with two salmonella strains, both of which were smooth and motile. In conformity with the results of previous workers, he finds these bacilli contain two antigens: (1) an antigen associated with the flagella, which gives rise to agglutinins of the floccular type; (2) an antigen associated with the body of the organism—somatic antigen—which produces agglutinins of the granular type. The flagellar antigen can be removed from suspensions of the bacteria either by shaking, followed by centrifugalization and rejection of the supernatant fluid, or by heating to 100° C. for half an hour. The deflagellated bacteria are incapable of giving rise to floccular agglutinin, but are still able to absorb some of the flocculating agglutinin from a whole serum; this may be the result of non-specific absorption. The presence of soluble precipitable material was demonstrated in small amount in culture filtrates, and in greater concentration in filtrates of heated suspensions. Most of this appeared to be of somatic origin, but a small amount was derived from the flagella. In another paper (ibid., p. 825) the author reports that if ordinary absorption mixtures of bacteria and serum are prepared, the bacteria centrifuged down and washed, and the resulting sensitized bacteria are suspended in 5 per cent. salt solution and heated to 60° C. for one hour, with frequent shaking, a considerable amount of the flagellar agglutinin is detached from the bacteria, but little or no somatic agglutinin. In practice, the extraction with salt solution was repeated two or three times, the mixtures were centrifuged, and the titre of the supernatant fluid was tested against the different antigens. By this means approximately 50 per cent. of the flagellar agglutinin could be removed. This observation adds further support to the view that the somatic and flagellar agglutinins are distinct.

The Haemorrhoidal Circle



Internal and external haemorrhoids resulting from pressure upon the blood vessels and obstruction of the circulation in the rectum.

DISTENTION of the rectum from painful defæcation—pressure on the rectal blood vessels — impeded circulation — hæmorrhoids. Cathartics to relieve the constipation —irritation of the mucous membrane and the existing hæmorrhoids — pain — possible anal fissure — cessation of purging—constipation.

Such is all too frequently the vicious circle of dyschezia and hæmorrhoids, a combination which requires appropriate local treatment and a bowel corrective that will not irritate.

AGAROL Brand Compound, the original emulsion of mineral oil, agar-agar and phenolphthalein, is pre-eminently indicated for the correction of the vicious circle.

AGAROL Brand Compound lubricates, therefore prevents irritation by friction; it segments and softens the fæcal mass, and thereby prevents possible excessive strain in the expulsion of it; it stimulates the peristaltic force without the shock of cathartics.

A liberal quantity sent to physicians on request.

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; *no* oil leakage; no griping or pain; no nausea; not habit forming.

The U.G.B. COMPLETE Medical Bottle Service

Packed in sealed non-returnable standardized fibre cartons.

CORK MOUTH SERVICE

SCREW CAP SERVICE

Washed & Sterilized— ready for use

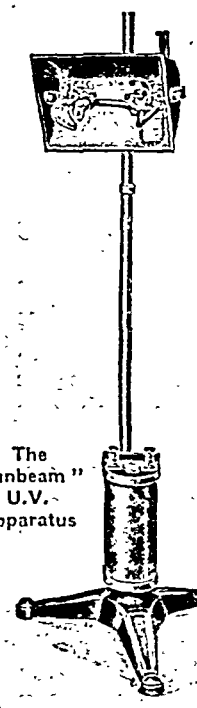
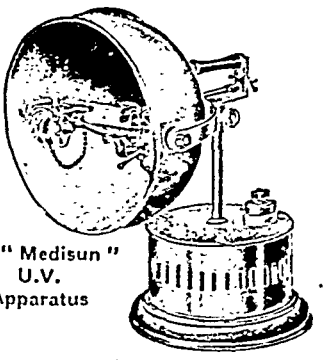
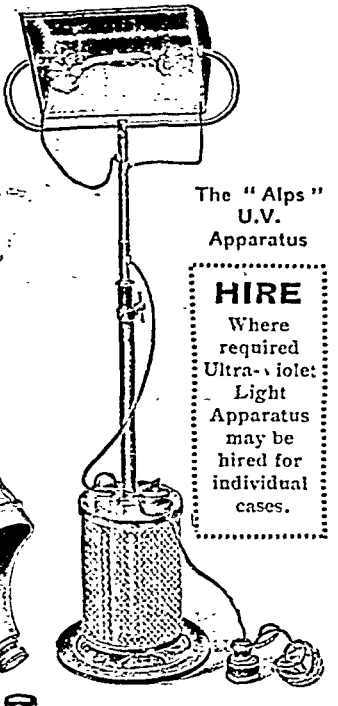
ULTRA VIOLET LIGHT



The "Sunbeam" U.V. Apparatus



The "Medisun" U.V. Apparatus



The "Alps" U.V. Apparatus

The models illustrated provide at economical cost a highly efficient source of Ultra-Violet Radiation. Widely approved by the Medical Profession on account of their simplicity and dependability, and 100% British.

ASK FOR LIST B 42

HIRE

Where required Ultra-violet Light Apparatus may be hired for individual cases.

THE "MEDISUN" U.V. APPARATUS

Quartz Mercury Vapour Type.

Designed for whole body or local applications. Suitable for general practitioners, or for use in the homes of private patients.

PRICE, for use on direct current - - £12
PRICE, for use on alternating current - - £18

"SUNBEAM" U.V. APPARATUS

Designed for Home Use, the Quartz Mercury Vapour Burner is less powerful than our other Models and consumes less current.

PRICE, for use on direct current - - £15 10s.
PRICE, for use on alternating current - - £25

THE "ALPS" U.V. APPARATUS

Designed for Home or Professional use.
Fitted with standard size Quartz Mercury Vapour Burner.

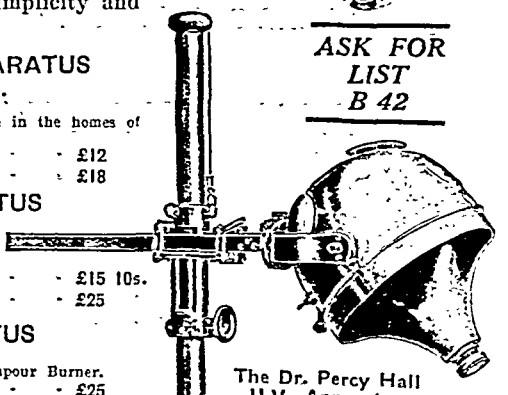
PRICE, for use on direct current - - £25
PRICE, for use on alternating current - - £41

THE DR. PERCY HALL U.V. APPARATUS

(Dual Purpose Model)

Provides in a single apparatus the means of applying Ultra-Violet Radiation either generally, locally, or internally by quartz applicators or specula. Acknowledged to be the most perfect type yet designed.

PRICE, for use on direct current - - £38
PRICE, for use on alternating current - - £53

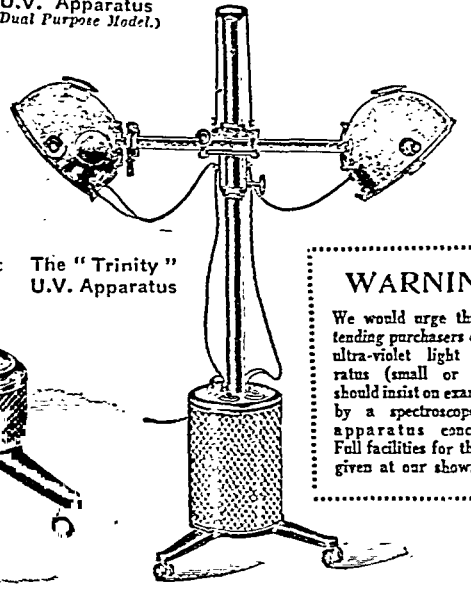


The Dr. Percy Hall U.V. Apparatus
(Dual Purpose Model.)

THE "TRINITY" U.V. APPARATUS

Designed to provide the radiation of Tungsten Arc, Carbon Arc, and Mercury Vapour Arc, so providing a selection of radiations at the will of the operator. Handsomely finished and made throughout in our own London Works

PRICE, for use on direct current - £41
PRICE, for use on alternating current - £55



The "Trinity" U.V. Apparatus

WARNING

We would urge that intending purchasers of any ultra-violet light apparatus (small or large) should insist on examining by a spectroscope the apparatus concerned. Full facilities for this are given at our showrooms.

The 20-h.p. Rolls-Royce

"I GIVE you my opinion of it, it being my 59th car and 8th Rolls-Royce. Straight away, I must say that this latest 20 is the most beautifully designed piece of mechanism I have ever come across, the whole chassis blending into one almost perfect machine, each part exactly suited to the next. The car runs more silently and sweetly than any other I know, the whole engine and transmission turning quietly and without vibration, whether in gear or not, just like a smooth running electric motor. The car runs in the indirect gears more silently and more sweetly than many another car on direct drive. I can find no trace of vibration in the engine at any speed. The gearbox, gear change, and back axle are ahead of any other make of car. The brakes are perfect, the springing is excellent and the steering is now very good indeed.

It is the easiest possible car to handle and one can drive it all day long with less anxiety and fatigue than any other car I know, in fact, with no fatigue at all."

Owner Driver's Letter, ref. 2011

SANALUX AND SUNSHINE

The benefits of the therapeutic ultra-violet rays of so'ar radiation are adequately proved. Thus, the advantages of SANALUX—a permeable glass, which admits practically unobstructed these preventive and curative vital rays—as a tonic and health bringer are innumerable.

SANALUX is a glass of exceptional transparency, admitting the highest possible degree of "static" transmission—a point of great importance when window glass of the ultra-violet type is advised and expected to produce tangible results.

SANALUX marks a considerable step forward in providing an effective and practical agent for the transmission of the essential therapeutic ultra-violet rays.

A treatise upon SANALUX and its health-giving properties will be gladly forwarded to anyone interested.

Sole Agents for South of England:

JAMES CLARK & SON, LTD., Railway Arches, Blackfriars Road, London, S.E.1.

Manufacturers: COURTAULDS LTD., 16, St. Martin's-le-Grand, London, E.C.1

QUALITY

People say, "Quality tells!" Before ordering a new suit or coat, consider what a great asset is a dependable Lining. It means many months' more wear, always a snug and easy fit, and no danger of shrinkage or discolouration. But only in "COURTINE" LININGS (woven only by Courtaulds Ltd.) are these advantages guaranteed. There is a full choice of colours and qualities, suitable for business, sports, or evening wear. Test and compare as you may—"COURTINE" LININGS will become a "standing order." Ask your Tailor.

"Courtine" (REGISTERED) LININGS

The name is on the Selvedge.

WYLEYS LIMITED WHOLESALE DRUGGISTS COVENTRY Established 1750.

RUSCOL.
(Registered Trade Mark)

An Organic Compound of Bismuth and Birch Tar.

Successful in cases of Eczema, Erysipelas, Pruritus, and all Skin Diseases.

PRICE 5/- lb.

FLUID EXTRACT OF MALT WITH GLYCEROPHOSPHATES & RED BONE MARROW.

Containing Glycerophosphates of Lime, Soda, Potash, Iron, and Magnesia, in combination with Extract of Red Bone Marrow.

PRICE 2/- lb.

ELIXIR BROMO-VALERIAN CO.

Free from any disagreeable taste or odour.

Each fluid drachm (4 c.c.) contains:

Strontii Bromidi ... 5 gr. Tinct. Adonis Vernalis 5 m.
Tinct. Valer. Deodorat. 10 m. Tinct. Visci Alb. ... 5 m.

Useful for functional nervous affections, particularly in controlling epileptic seizures.

PRICE 5/- lb.

AROMATIC CASCARA.

An agreeable and physiologically active preparation almost devoid of bitterness, which represents the therapeutic virtues of Cascara Sagrada.

PRICE 6/6 lb.

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS.
Medical prescriptions made up to the minutest detail.

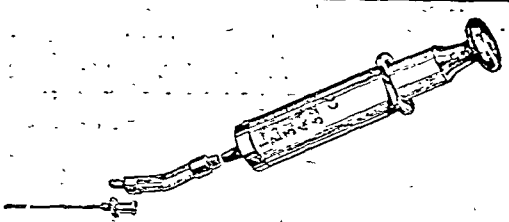
SPECIAL SYRINGES
FOR
The INJECTION TREATMENT of VARICOSE VEINS



The Special Features:

(1) The angled nozzle of the syringe ensures a perfect view of the point at which the injection is being made.

(2) The angled glass capillary tube has a white opaque background, and therefore renders a minute column of blood easily visible.

(3) The syringe is strongly made, and may be sterilized by boiling in water.

Syringe for varicose veins, with graduated glass barrel and amber glass plunger, with metal nozzle, and detachable capillary tube with opaque background, with two stainless steel needles on movable rack in nickel-plated metal case.

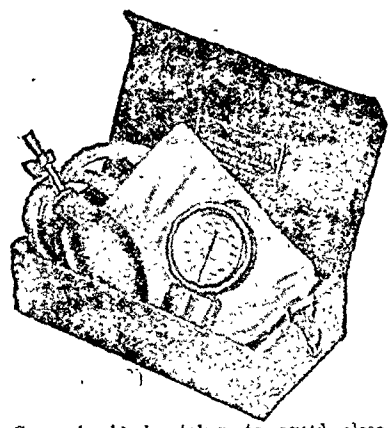
Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

EATAN
Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-Irritant.

Dr. Hall, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for Invalids.

Issued in 2/6, 4/-, and 12/- bottles.

Special Terms to Hospitals.

THE PREMIER DENTIFRICE

Vapo-Cresolene Est. 1879
Sold by all Chemists
Write for descriptive Booklet No. 67B.

ASTHMA
There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.
This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

PRIVATE PATIENTS are received at a weekly charge of TWO GUINEAS and upwards.
Voluntary BOARDERS can now be admitted.—Apply to the MED. SUPERINTENDENT.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: The Most Hon. the Marquess of Exeter, C.M.G., A.D.C.

Medical Superintendent: Daniel F. Rambaut, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

Administrative County of Surrey

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Surrey invite applications from duly qualified medical practitioners holding a Diploma of Public Health for the office of County Medical Officer of Health.

The person appointed will be required to act as Head of the County Medical Services and to perform any additional duties relating to Public Health which may be imposed upon the Council by new legislation.

The remuneration will be a net personal salary of £1,800 per annum.

The appointment is designated an established post under the Local Government and Other Officers Superannuation Act, 1922, and will be held subject to the provisions of that Act, to the Orders for the time being of the Minister of Health, and to the Standing Orders of the Council.

Applications on the prescribed form (which, with a general statement of the conditions and duties of the office, may be obtained from me on receipt of a stamped and addressed envelope), accompanied by copies of not more than three recent testimonials, must be sent in a sealed envelope marked "C.M.O.H.," to reach me at the underwritten address not later than Thursday, February 28th.

Canvassing by or in favour of a candidate will disqualify the applicant.

County Hall, Kingston-upon-Thames. February 1st, 1929.
DUDLEY AUCKLAND, Clerk of the Council

Metropolitan Borough of BETHNAL GREEN.

MEDICAL OFFICER OF HEALTH.

The Bethnal Green Borough Council invite applications for the appointment of Medical Officer of Health at a commencing salary of £1,000 per annum, rising by annual increments of £50 on approved service to a maximum salary of £1,200 per annum, inclusive of all services of any kind whatever.

Candidates must not be over 45 years of age, and must possess the qualifications prescribed by the Public Health (London) Act, 1891, and the Sanitary Officers Order, 1926.

The appointment will be subject to the approval of the Ministry of Health, to the candidate satisfactorily passing a medical examination, and to the Superannuation Act, By-laws, and Standing Orders of the Council.

Applications must be on forms obtained from me, and returned so as to reach me at the Town Hall, Bethnal Green, London, E.2, by noon on Tuesday, March 5th.

Canvassing will disqualify a candidate.

DAVID J. KEEP, Town Clerk.

Nottinghamshire.

APPOINTMENT OF COUNTY MEDICAL OFFICER.

Applications are invited for the appointment of MEDICAL OFFICER OF HEALTH for Nottinghamshire from duly qualified persons, and preference will be given to those applicants who have already had experience of the work of a Medical Officer of Health.

The salary will be £1,200, rising by four annual increments of £50 to £1,400 per annum, and offices, staff, stationery, and travelling expenses will also be provided.

A print of the conditions and duties appertaining to the appointment can be obtained on application to me.

Applications, giving particulars of experience, qualifications, and medical degrees, must be forwarded to me, together with copies of not more than three recent testimonials, marked "County Medical Officer of Health," not later than Monday, March 4th.

County House, Nottingham. February, 1929.
K. TWEEDALE MEABY, Clerk of the County Council.

County Borough of Newport.

MENTAL HOSPITAL.

ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the above post. Candidates must be under 35, unmarried, and preferably with previous experience in Mental Diseases. Commencing salary £300 per annum, with apartments, board, and laundry. Appointment pensionable under Asylum Officers Superannuation Act, 1909.

Applications, stating age, qualifications, and previous experience, accompanied by copies of three recent testimonials, must reach the undersigned by Monday, the 25th instant.

Town Hall, Newport, Mon. February 4th, 1929.
O. TREHARNE MORGAN, Town Clerk.

County of London.

The London County Council invite applications for appointment, as EIGHTH ASSISTANT MEDICAL OFFICER (male) in the MENTAL HOSPITAL SERVICE. Candidates must be under 35 years of age, and be registered to practise both in Medicine and Surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, making the present total commencing remuneration approximately £414 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. Candidates appointed will be pensionable under the Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Thursday, February 21st. Canvassing disqualifies.

MONTAGU H. COX, Clerk of the London County Council.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculosis and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Thursday, February 28th. Canvassing, directly or indirectly, will disqualify.

County Hall, Kingston-upon-Thames. Feb 12th, 1929.
DUDLEY AUCKLAND, Clerk of the County Council.

Metropolitan Asylums Board.

Applications are invited for the appointment of JUNIOR ASSISTANT MEDICAL OFFICER at GROVE PARK HOSPITAL, LEE, S.E.12 (322 beds) for Adult (male and female) cases of Tuberculosis. Most of the accommodation is for advanced pulmonary cases, but there is a certain number of beds for surgical cases, and some experience in surgery and orthopædics is desirable. There is no accommodation at the Hospital for a married officer. Preference will be given to candidates under 30 years of age. Salary £500 per annum. There are three other medical officers on the staff.

The candidate appointed will be required to reside in the Institution and pay for board, lodging, and washing at the rate fixed from time to time by the Board's Finance Committee. At present the rate is £130 per annum.

Application to be made not later than 10 a.m. on Wednesday, February 27th, on form obtainable from the Clerk, Metropolitan Asylums Board, Victoria Embankment, E.C.4, by forwarding stamped addressed foolscap envelope.

ALLAN POWELL, Clerk to the Board
Feb. 12th, 1929.

Mansfield and District Hospital.

The Board of Management of the above Hospital (130 beds) invite applications for the post of SENIOR HOUSE SURGEON (male).

Salary at the rate of £200 per annum, with residence, board, and laundry. The appointment is for six months and is renewable. Duties to commence on March 1st.

Candidates must have held previous Hospital appointment. There is ample scope for good operative work.

Applications, accompanied by not more than three recent testimonials, to be sent to the undersigned.

Dated this 12th day of February, 1929.

ARTHUR H. LIMB, Secretary.

EAST AFRICAN MEDICAL SERVICE

APPOINTMENTS

VACANCIES exist at present for MEDICAL OFFICERS and HEALTH OFFICERS in the EAST AFRICAN MEDICAL SERVICE.

Candidates should be British subjects of European parentage and not over 35 years of age. Preference will be given in the case of Medical Officers to candidates who have held House appointments as House Physicians and House Surgeons. In the case of Health Officers a Diploma in Public Health is essential. Candidates should apply, in writing, to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, London, S.W.1, for the necessary forms of application.

SALARIES.

MEDICAL OFFICERS £600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by increments of £40 to £920 per annum.

HEALTH OFFICERS enter the scale at £660.

QUARTERS.

Free quarters are provided, or an allowance is given in lieu.

PASSAGES.

Free first-class passages are provided, both on first appointment and when proceeding on leave. A married officer will be granted an allowance towards the cost of his family's passage once each way in respect of each tour of service.

University of Lucknow.

Applications are invited for the PROFESSORSHIP OF MEDICINE and PHYSICIAN to KING GEORGE'S HOSPITAL, attached to the University. Salary Rs.1,200—50—1,400 per mensem, plus benefits of the University Provident Fund on confirmation (rate: 8 per cent. of salary paid by subscriber and 8 per cent. by the University). Consulting practice allowed. The selected candidate will be on probation for one year and will be required to join the Lucknow University about November 1st, 1929. Applications, stating age, academic qualifications, hospital experience, and research publications, with copies of three testimonials, should reach the Registrar, Lucknow University, Lucknow, on or before March 31st

NOTE.—For members of the Indian Medical Service the conditions of service will be similar to those of Government servants holding similar appointments.

R. R. KHANNA, Registrar.

Hong-Kong.

The Government of Hong-Kong requires the services of a MEDICAL OFFICER.

Salary.—£600 per annum, rising by annual increments of £30 to £1,020 per annum.

Quarters.—Furnished quarters are provided at a rental of approximately 6 per cent. of salary, or an allowance is given in lieu.

Passages.—Free passages are provided on first appointment and when proceeding on leave.

Qualifications.—Applicants should be under 35 years of age. Preference will be given to candidates who have held House appointments as House Physicians and House Surgeons.

Further particulars and forms of application may be obtained on application, in writing, to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, S.W.1.

Torbay Hospital, Torquay.
(142 Beds.)

HOUSE PHYSICIAN wanted for about March 14th. Salary £150 per annum, with board, residence, and laundry. Candidates must be fully qualified, registered, and unmarried.

Applications, stating age, nationality, qualifications, and experience, must be received by the undersigned on or before Tuesday, February 25th, with copies of not more than three recent testimonials.

E. L. GRIST,
February 11th, 1929. Secretary.

Northern Rhodesia.

The Government of Northern Rhodesia requires the services of a MEDICAL OFFICER.

Emoluments.—£600 per annum, rising by annual increments of £30 to £840 per annum, then by annual increments of £40 to £920 per annum.

Conditions of Service.—The appointment is pensionable, subject to a probationary period of two years in the first instance.

Passages.—Free passages are provided both on first appointment and when proceeding on leave. An allowance is granted in the case of a married officer towards the cost of his family's passage once each way in respect of each tour of service.

Quarters.—Free quarters are provided, or an allowance in lieu is paid.

Further particulars and forms of application may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, London, S.W.1.

Completed applications must reach the Private Secretary by March 9th.

Dorset Mental Hospital,
DORCHESTER.

SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from candidates duly qualified, registered, and unmarried. Commencing salary £400, rising by two yearly increments of £25 to £450, with board, apartments, laundry, and attendance.

Excellent laboratory facilities exist with skilled assistance for research and clinical medicine. (900 Beds.) The appointment is subject to the provisions of the Asylum Officers Superannuation Act, 1909.

Applications, stating age and qualifications, with copies of recent testimonials, should be sent to the Medical Superintendent at once.

February 11th, 1929.

Cardiff Royal Infirmary.

OPHTHALMIC HOUSE SURGEON required immediately. Applicants must have a knowledge of refractions. This post is open to ladies.

Salary at the rate of £75 per annum, with board and lodging. The appointment is for six months.

Applications, with copies of three recent testimonials, should be submitted as soon as possible to the undersigned.

R. ARMSTRONG,
February 9th, 1929. Medical Supt.

[AMENDED ADVERTISEMENT]

Rochford Hospital.

MALE ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of Male Assistant Resident Medical Officer at the Hospital, Rochford, near Southend-on-Sea. The appointment will, in the first instance, be for twelve months, with salary at the rate of £300 per annum. If the officer is re-appointed after twelve months' service the salary will be increased to £350 per annum. In addition, arrangements will be made for the officer to be provided with apartments, laundry, and maintenance outside of the Hospital to the limit of £200 per annum. The salary and value of emoluments are subject to deductions under the Poor Law Officers Superannuation Act, 1896. Applicants must be fully qualified, and must have had at least two years' resident Hospital experience. He will be required to take charge of the Hospital during the absence of the Resident Medical Officer.

The Rochford Hospital at the present time contains 380 beds, and this number will be increased in a short time. The Hospital is recognised as a complete Training School for Nurses. The Resident Medical Staff will number three. A wide experience of Medical and Surgical work is to be obtained. It is desired that candidates shall have had practical experience of Surgery and Anæsthetics. It may be stated that there are many opportunities in the neighbourhood for golf and other sports.

Application forms, which must be properly filled in, and returned to me not later than March 1st together with further particulars of the appointment, can be obtained from the undersigned on receipt of a stamped addressed foolscap envelope.

By Order,
W. HARDING ROBERTS, Clerk.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns., 40 to 50 cases yearly. Large house (having eight or nine rooms, with garden, etc), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
2. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 3/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
3. NORTH STAFFORDSHIRE.—Old-established mixed general Country PRACTICE, situated in very delightful district, and offering scope. Average income about £1,000, including Poor Law appt. and panel of 660. Fees 3/6 to 10/6. Good house, on lease, rent £84 p.a. Excellent schools within reach. Premium 1½ years' purchase.
4. BUCKS.—GROWING COUNTRY DISTRICT.—Old-established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6 Little midwifery. Good freehold house, price £1,500, part on mortgage. Sport of all kinds. Knowledge of refractions advantageous. Premium £850.
5. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 3/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
6. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Introduction of six months if required.
7. LONDON, S.E. (CROYDON AREA).—Old-established rapidly increasing middle-class PRACTICE. Income for immediate past year over £1,300, including panel of 700. Surgery fees 2/6 to 5/-. Visits 3/6 to 10/6 Thirty midwifery cases yearly from 3 to 10 guineas. Very commodious house on lease, with 11 years to run, rent £70. Premium £2,000.
8. WITHIN ONE MILE OF MARBLE ARCH.—PARTNERSHIP.—A Half Share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 3/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position. Held on lease (with no ground rent) with 25 years to run. Price £1,750. Premium £4,000. Must be Scotch or English.
9. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
10. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
11. SOUTH-EAST OF ENGLAND.—COAST TOWN.—Small but increasing PRACTICE, at present producing about £500 per annum, with good scope. Panel of 420 Suitable house available. Rent £52 p.a. Premium £500, part down, and balance by instalments
12. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium £750.
13. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525 and appointments worth over £60 p.a. Advice and medicine clubs 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
14. [illegible] OF LARGE TOWN.—Old-established PRAC[illegible] years. Average income for the past twelve months £1,000, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
15. OUTLYING WESTERN SUBURB.—Old-established mixed general PRACTICE. Income for the immediate past year about £2,500, including panel of between 1,400 and 1,500. Fees 3/6 to 10/6 Midwifery from 3 gns. The district is rapidly developing and there is great scope. Good house, with garden and garage. Price £2,000. Premium £3,500.
16. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns (about 40 cases yearly. Moderate expenses Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden Brick built garage. Price for freehold £1 500 Premium £4,500
17. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery, 2 gns. upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300 Premium £1,400.
18. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1¼ acres, and 12 acres of grassland. Recently re-decorated throughout Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.

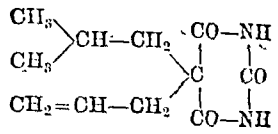
SANDOPTAL



A NEW HYPNOTIC

ISOBUTYL-ALLYL-MALONYLUREA

Clinical and laboratory tests have shown that Sandoptal fulfils to a high degree the conditions required in a hypnotic agent.

Sandoptal owes its advantages to a particularly favourable therapeutic index which permits sufficient dosage without harmful after-effects.

Sandoptal is sure and constant in action, and well tolerated by the aged.

It produces tranquil sleep of natural intensity and normal duration, and the awakening is net and accompanied by a feeling of freshness and general well-being.

It has been shown that Sandoptal is rapidly eliminated from the organism and that it does not produce exanthema.

DOSAGE:

Usual dose: 1 tablet, half to one hour before bed-time.

In obstinate cases: 1 to 3 tablets may be given (maximum dose 4 tablets).

TUBES OF 10 AND BOTTLES OF 100 TABLETS.

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready solubility in water. Well tolerated. Absence of local reaction on injection.

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Physicians are invited to write for further particulars and clinical trial samples.

New Books—New Editions

Babcock's Surgery

IMMEDIATELY SUCCESSFUL

Dr. Wayne Babcock's book is complete. It contains a full discussion of general surgery, minor surgery, major surgery, the diagnosis of surgical conditions and their treatment—medical, surgical, or both, as indicated. The 1,050 illustrations, 9 in colours, are nearly all original and have been specially drawn under Dr. Babcock's supervision. They are clear and instructive. Frequently the right way is contrasted with the wrong way of doing things and points of particular importance are indicated.

Octavo of 1,567 pages, with 1,050 illustrations, 9 in colours. By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Cloth, 45s. net

Bethea's Clinical Medicine

CHAPTER ON EPIDEMIC INFLUENZA

Dr. Bethea has written for that great group of practitioners away from the medical centres who must depend largely on trained senses of touch, sight, and hearing. It is a bedside medicine in the truest sense.

Octavo volume of 700 pages, illustrated. By OSCAR W. BETHEA, M.D., Professor of Clinical Medicine, Tulane University School of Medicine, New Orleans. Cloth, 35s. net

McGuigan's Therapeutics and Pharmacology

NEW

Dr. McGuigan wrote with a definite objective—viz., to give a clear statement of the important facts of pharmacology and therapeutics, to show the basis for these facts, and to make clear their application. Theory is wedded to practice.

By HUGH ALISTER MCGUIGAN, PH.D., M.D., Professor of Pharmacology and Therapeutics, University of Illinois College of Medicine. Cloth, 28s. net

Foster's Examination of Patients

SECOND EDITION

In addition to a record of all the important advances, this new (2nd) edition contains new—brand new—sections on the febrile diseases, the anemias, the endocrines, the muscles, joints, bones, and vessels, and a greatly expanded section dealing entirely with tests.

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 253 pages, with 70 illustrations, a number in colours. Cloth, 21s. net

Graves' Gynecology

FOURTH EDITION

A new work—that's what this edition really is, because the revision was so extensive that it amounts to re-writing. Whole sections have been cut out, others have been completely re-written, new chapters have been inserted, old material that was retained received new form because of omissions, corrections, and additions.

Octavo volume of 1,016 pages, with 562 illustrations, 123 in colours. By WILLIAM P. GRAVES, M.D., Professor of Gynecology at Harvard Medical School. Cloth, 48s. net

DeLee's Obstetrics

FIFTH EDITION

Both text and illustrations received careful revision in the preparation of this Fifth Edition. The greatest increase was made in those sections devoted to the work of the general practitioner. Dr. DeLee added many new illustrations, and re-wrote completely many of the chapters.

Octavo of 1,140 pages, with 1,128 illustrations, 201 in colours. By JOSEPH B. DELEE, M.D., Professor of Obstetrics at the Northwestern University Medical School, Chicago. Cloth, 55s. net

Labat's Regional Anesthesia

NEW (2nd) EDITION

Dr. Labat has subjected his work to a very thorough revision, some chapters having been entirely re-written. In addition 68 new illustrations have been added. New advances, new instruments, new technic are all given here clearly and definitely.

Octavo of 567 pages, with 367 illustrations. By GASTON LABAT, M.D., Clinical Professor of Surgery, New York University and Bellevue Hospital Medical College. Cloth, 35s. net

W. B. SAUNDERS COMPANY LTD. 9, Henrietta Street LONDON, W.C.2

OXFORD MEDICAL PUBLICATIONS.

THE TREATMENT OF
Chronic Arthritis and Rheumatism

By H. WARREN CROWE, D.M., B.Ch.(Oxon.), M.R.C.S., L.R.C.P.

"Deserves the careful consideration of all physicians."—*Glas. Med. Jour.*
"Writes in an interesting and persuasive manner. The trial of his methods by impartial practitioners is certainly desirable."—*Lancet.*
"The details of treatment are carefully laid down."—*Brit. Med. Jour.*
"His views on the bacteriology are clear-cut and interesting."
—*Caledonian Medical Journal.*
"We have to thank Dr. Crowe for having described his methods so minutely."—*Irish Journal of Medical Science.*

BACTERIOLOGY AND SURGERY OF
Chronic Arthritis and Rheumatism
With End Results of Treatment

Pp. 197. 6 Col. Plates. 34 Illus. 4 Charts. 30s. net.

"The basis and the supplement to Dr. Warren Crowe's earlier volume... sets out in full his bacteriological conclusions . . . contains the grounds for (his) views as to the etiology . . . there is much to excite thought and critical consideration in these pages."—*British Medical Journal.*
"To be congratulated on the excellence of his photographs and of his colour process reproductions."—*Lancet.*
"Has obtained practical results of far-reaching importance . . . deserves careful study alike by clinicians and laboratory workers."
—*Newcastle Medical Journal.*

The Oxford University Press

HUMPHREY MILFORD (And of all Booksellers) Dept. R., Falcon Sq., London, E.C.1

THIRD EDITION (3rd IMPRESSION). Crown 8vo. 4s. net, postage 2d.

THE INJECTION TREATMENT OF VARICOSE VEINS

By A. H. DOUTHWAITE, M.D., M.R.C.P.Lond.

"The ambulant treatment of varicose veins and haemorrhoids has recently attracted great interest among all grades of our profession, and Dr. Douthwaite has summed up our present knowledge of the treatment in a most readable and clear manner. . . . We can commend the book most heartily to our readers."—GLASGOW MEDICAL JOURNAL.

LONDON: H. K. LEWIS & CO. Ltd., 136, GOWER STREET, W.C.1.

LEWIS'S PUBLICATIONS.

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment.

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. & Edin., Surgeon to the Hospital for Women, Soho Square, London; Gynaecological Surgeon to the Kensington, Fulham, and Chelsea Hospital; Author of "The Effects of Radium upon Living Tissues," etc.

"The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study."—THE LANCET.

SECOND EDITION. Eighth Impression. Post 8vo. 7s. 6d. net.; post 6d.

ÆQUANIMITAS: With other Addresses to Medical Students, Nurses, and Practitioners of Medicine.

By Sir WILLIAM OSLER, Bart., M.D., F.R.S., late Regius Professor of Medicine, University of Oxford, etc.

"Written with all the breadth of view and the beauty of style which make Professor Osler's writings so characteristic and so valuable."
THE LANCET.

London: H. K. LEWIS & Co. Ltd., 136, Gower St., & 24, Gower Place, W.C.1.

That book you want! Foyles can supply it. Special Department for Books on Medicine, Surgery, Nursing, and allied subjects. URINARY SURGERY A Handbook for the General Practitioner

By W. K. IRWIN, M.D., F.R.C.S.,
Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

¶ "Clearly written . . . furnishes the practitioner with information of great practical value in his everyday work."—*British Medical Journal.*

SECOND EDITION. Revised and Enlarged. Price 10s. 6d. (postage 6d.).

BAILLIÈRE, TINDALL & COX, 7 & 8, Henrietta St., London, W.C.2.

"BANISH TRUSS TORTURE"
AND SECURE ACCURATE ABDOMINAL SUPPORT AND COMFORT FOR YOUR PATIENTS BY RECOMMENDING THE
"ROSE CORSET-BELT"

which has proved so effectual in all abdominal cases. The X-ray has shown the actual uplift.

Each Corset-Belt is cut and fitted to individual requirements, and the patient is kept under observation until every satisfaction is given to both patient and doctor.

I have also invented an improved Colotomy Belt for both male and female patients.

My work is recommended by eminent members of the medical profession, and the following hospitals: St. Bartholomew's Hospital, Metropolitan, Charing Cross, Middlesex, London Temperance.

Please note new address.

PROTOZOOLOGY

A Manual for Medical Men

By JOHN GORDON THOMSON, M.A., M.B., Ch.B., Director, Department of Protozoology, London School of Hygiene and Tropical Medicine.

AND

ANDREW ROBERTSON, M.B., Ch.B., Lecturer and Milner Research Fellow in the Department of Protozoology, London School of Hygiene and Tropical Medicine.

This work gives a clear account of the morphology and mode of life of the protozoal parasites which are important as the cause of disease in man, and, at the same time, describes their life-histories, on a knowledge of which can be based intelligent preventive measures. The pathology of the various diseases in man is also dealt with.

NOW READY. Size 9½" × 6½". Pp. xii + 304. With 200 Illus. Price 30s. Postage: Inland, 9d.; Abroad, 1s.

HELMINTHOLOGY: MEDICAL & VETERINARY

By H. A. BAYLIS, M.A., D.Sc., Assistant Keeper, Department of Zoology, British Museum (Natural History).

This work gives a full account of the numerous species of worms parasitic in man and the domestic animals. The available descriptions of many of these have, until now, been scattered through a vast mass of periodical literature which has not been readily accessible.

NOW READY. Size 7½" × 5". Pp. xii + 200. Price 6s. Postage 6d.

GLEANINGS FROM GENERAL PRACTICE

By DAVID TINDAL, M.D., F.R.F.P.S.(Glasgow).

"I have set down in these pages a few counsels on professional conduct and on medical subjects gathered from my long experience . . . in the hope that they may prove of service to some of the younger men and women."
—Extract from Preface.

NOW READY. In the Minor Monograph Series. Price 5s. Postage 3d.

VARICOSE VEINS

AND THEIR TREATMENT BY "EMPTY VEIN" INJECTION

By RONALD THORNHILL, M.B., Ch.B.

With Foreword by Sir Berkeley Moynihan.

"A simple, safe, and quick device." BRIT. MED. JOUR.
"The book is enhanced in usefulness by the fact that the writer has been content in the main to concentrate on only one method, and to mention other methods but briefly."
—LANCET.

NOW READY. SECOND EDITION. Pp. x + 231, with 9 Plates and 30 Illus. Price 12s. 6d. Postage 8d.

PHYSIOTHERAPY IN GENERAL PRACTICE

By E. BELLIS CLAYTON, M.B., B.Ch.(Cantab.),

Director of the Physiotherapeutic Department at and in charge of the Massage and Electrical School, King's College Hospital, London.

"The treatment by physiotherapy of most conditions requiring this form of treatment in general practice is discussed in detail, and the book is illustrated by excellent diagrams and photographs. . . . We congratulate the author on his enterprise in producing a book which should prove of great value."—GLASGOW MEDICAL JOURNAL.

NOW READY. SECOND EDITION. THOROUGHLY REVISED, with the addition of Two New Chapters.

BIGGER'S BACTERIOLOGY

". . . In this book the author has succeeded admirably in expounding the principles of bacteriology free from the confusion of its many special refinements."—GUY'S HOSPITAL GAZETTE.
". . . It can be confidently recommended to those wishing to obtain a well-written, sound book of bacteriology of a reasonable length."—ST. BARTHOLOMEW'S HOSPITAL JOURNAL.

Size 8" × 5½". Pp. xvi × 452, with 5 Coloured Plates and 82 other Illus. Price 12s. 6d. Postage 9d.

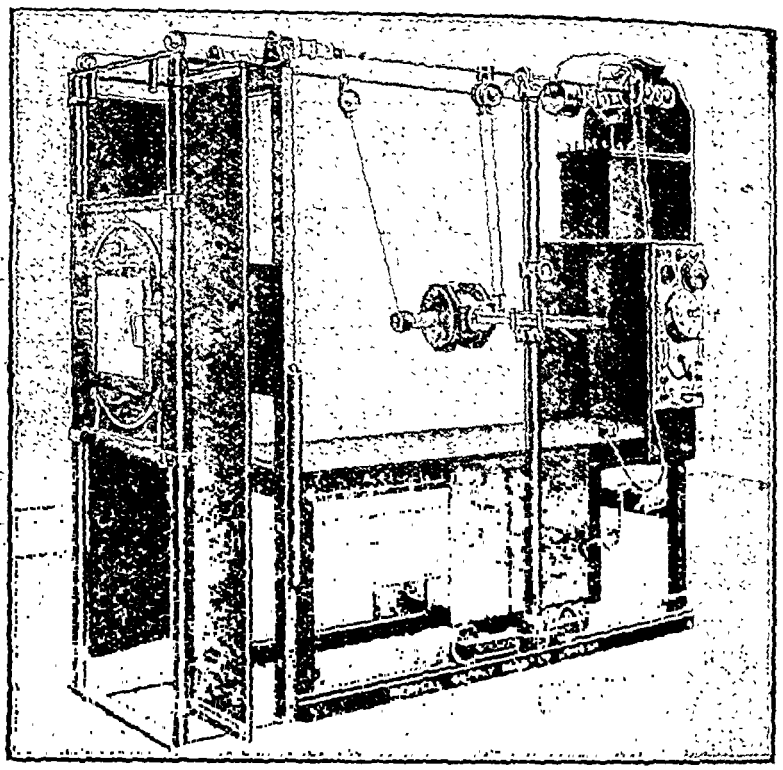
EXPERIENCE

with

The

N.P.L.



THE CERTIFICATED APPARATUS.

UNIVERSAL X-RAY APPARATUS

"You switch on—we do the rest!"

This apparatus is exactly what its name implies—a universal X-ray Apparatus. It provides for radiography (general, dental, compression); radiotherapy; horizontal screening; vertical screening. It is the ideal all-round X-ray equipment for hospital, clinic, or private practice.

The UNIQUE TECHNIQUE DIRECTOR has revolutionised radiography. By the turning of a knob, it gives automatically every factor required for producing successful radiograms with certainty. These factors obtained, the setting of the controls is the essence of simplicity.

The N.P.L. APPARATUS GIVES FULL PROTECTION. It is unconditionally certificated by the National Physical Laboratory as complying with the recommendations of the X-ray and Radium Protection Committee.

The N.P.L. Universal X-Ray Apparatus is extremely compact. It occupies a floor space of only 7 ft. 6 in. × 2 ft. 8 in.

Price, complete with all Accessories for Alternating Current - £300

" " " " Direct Current - - £345

Being entirely of British manufacture, this apparatus is free of importation duty.

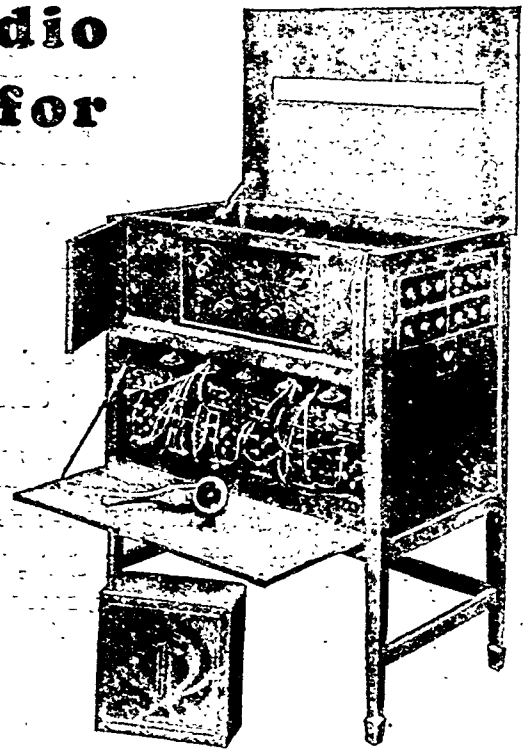
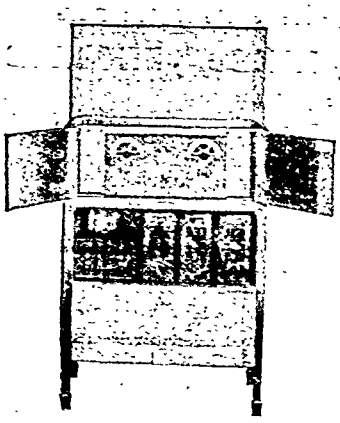
THE LARGEST X-RAY AND ELECTRO-MEDICAL SHOWROOMS IN THE BRITISH EMPIRE.

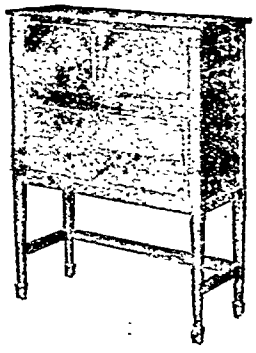
An Ideal Radio Installation for Hospital Entertainment



The Lodge Moor Hospital 9-Valve installation open, showing compact arrangement of eliminators, controls, etc.



Front View of a 6-Valve Met-Vick Hospital Set.



Met-Vick Hospital Set closed, showing attractive, substantial cabinet.

The above illustration shows the Met-Vick Set supplied to the Lodge Moor Hospital, Sheffield. It is capable of operating 40 loud speakers, and 450 pairs of headphones, and is operated direct from the electric light mains.

Met-Vick Hospital Sets can be supplied for operation of any number of loud speakers and phone points with controls which enable the complete installation to be started up or shut down, or alternatively, individual sections may be controlled without interference with the rest of the installation.

There is no trouble from Batteries or Accumulators, all current being supplied direct from the Mains through Met-Vick L.T., H.T. and G.B. eliminators. Low cost of operation, minimum amount of attention, together with reliability and safety, make a Met-Vick Hospital Set, an ideal installation for any institution.

Highly Nourishing

yet assimilable even by the weakest digestion

This food is an indispensable addition to the diet of expectant or nursing mothers

AS a constituent of the diet of the expectant or nursing mother and in all cases of dyspeptic or febrile disorders where a highly nourishing food is required in an easily assimilable form the value of Horlick's Malted Milk has long been recognized by the medical profession.

Prepared from fresh, full-cream cows' milk, selected wheat and malted barley, it constitutes a perfectly-balanced diet containing fat, proteins and soluble carbohydrates in correct nutritive ratio. It retains the vitamin content of its ingredients unimpaired throughout the process of manufacture.

Beneficial in relieving sickness

The high proportion of valuable malt sugars which Horlick's contains, and the fact that it is partially pre-digested during manufacture, make it assimilable even by weak digestions. It can often be taken at times when other foods, particularly foods prepared with ordinary fresh cows' milk, are distasteful or indigestible. Moreover, taken first thing in the morning, Horlick's has proved extremely beneficial in relieving morning sickness and other discomforts of pregnancy.

The easy digestibility and high carbohydrate content of Horlick's Malted Milk give it importance also as a galactogogue.

Horlick's Malted Milk is obtainable everywhere in sealed glass bottles at 2/-, 3/6, 8/6 and 15/-; also in tablet form.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Therapeutic Ointments

Ung. Renaglandin and Ung. Renaglandin Anaesthetic . .

Invaluable in Hæmorrhoids—Styptic.

Ozoline . . . An ideal method of employing the detergent action of Hydrogen Peroxide.

Ung. Iodsam . . A stainless ointment containing 10% of Iodine. Useful in Rheumatic affections, Tinea and Ringworm.

Ung. Zoleas . . A combination of Zinc and Mercury Oleates; Invaluable in dry and chronic Eczema, especially of gouty origin.

Local Anæsthesia in Surgical Practice

OPERATION ON NECK AND REMOVAL OF TESTICLE.

Typical Case.

S. J., male, aged 72 years.

Diagnosis: (1) Tuberculous cervical adenitis; (2) Tuberculous epididymitis and orchitis (right side).

Operation: (1) Block dissection of neck; (2) Right orchidectomy.

Anæsthesia: 77 c.c. of 0.5 per cent. Novocain-Adrenaline solution.

Operation: An infiltration block of the ilio-inguinal and ilio-hypogastric nerves, and as the cord was exposed it was thoroughly infiltrated. The pudic nerves were blocked, and the tuberculous testicle and epididymis were removed. The patient was allowed to leave the hospital in a few days, and he returned on March 3rd, 1920, at which time he had a complete dissection of the right side of his neck, using 120 c.c. 0.5 per cent. Novocain-Adrenaline solution.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Coated Tongue and Toxemia

Coating on the tongue consists of epithelial cells, molds, yeast, and many bacteria, some highly virulent. Normally the saliva prevents growth of the latter. If the resistance of the blood is lowered, the saliva loses its germ-destroying and inhibiting power. A tongue coating appears.

In the constipated colon, putrefactive bacteria produce highly active poisons such as skatol, indol, etc. These enter the blood, lower its resistance, and thus weaken all fluid secretions such as the saliva. No wonder 85 per cent. of all sick people have coated tongues. Constipation is almost universal among the sick.

If the tongue indicates toxemia, prescribe Nujol—the safe and effective treatment. Many intestinal toxins are themselves absorbed by Nujol.

Nujol

REGISTERED TRADE MARK

Once absorbed by Nujol, intestinal toxins cannot be absorbed by the system, as Nujol itself is non-absorbable.

Distributors for NUJOL LABORATORIES

ANGLO-AMERICAN OIL CO., LTD., Albert Street, Camden Town, London, N.W.1

In Infancy

WHETHER the child be breast-fed or bottle-fed, constipation is often a troublesome feature. Castor oil and other purgatives, or aperients, while securing a prompt action of the bowels, possess certain definite disadvantages with which the practitioner is fully acquainted.

"Cristolax," a combination of 50% of the purest medicinal paraffin of correct viscosity and 50% "Wander" Dry Malt Extract, is of special value for infants, particularly for those who are artificially fed. One teaspoonful dissolved in three feeds a day, no matter whether they consist of milk or infants' food, renders the feeds more easily digestible, prevents the formation of hard indigestible clots, and keeps the bowels in a regular and sweet condition.

"Cristolax" is also an admirable preparation for the nursing mother, both during gestation and the lying-in period. Its use ensures regular and adequate defecation without griping, straining, or harmful effect upon the child.

INFLUENZA

The nasal and oral cavities are the usual route of infection. Mistol applied with a Mistol dropper in the nose is an ideal preventive. Being an oily preparation Mistol diffuses and spreads itself in a thin film over all parts of the mucous membranes of the nose and throat. It clings tenaciously to mucous membranes, and is not easily washed away by the natural secretions. Thus it affords relief in all inflamed and irritated conditions, and assists in warding off infection.

Sold in original sealed cartons containing a—

In the treatment of
Asthma and Whooping-cough

EPHEDRINE B.D.H.

(The Naturally-occurring, Pure, Laevo-rotatory Product)

Clinical evidence shows that in recurrent asthma it is essential that the ephedrine employed be absolutely pure and free from all traces of pseudo-ephedrine; further, the superiority of naturally-occurring, laevo-rotatory ephedrine over the synthetic product—a mixture of dextro and laevo-ephedrine—has been established (*Lancet*, August 4th, 1928, page 226, and *Archiv für Experimentelle Pathologie und Pharmakologie*, 1928, 138, 209), the physiological activity of the naturally-occurring, laevo product being four to five times that of dextro-ephedrine and approximately double that of the synthetic compound.

Ephedrine Hydrochloride B.D.H. is prepared in the B.D.H. chemical works from the genuine Chinese plant Ma Huang by a special process whereby a perfectly pure product is obtained to the exclusion of pseudo-ephedrine.

OBESITY and its TREATMENT

"INKRETAN"

TABLETS

A Brominated preparation of Thyroid and Pituitary Glands, of standardised potency. Each "Inkretan" tablet contains 0.2 mgm. of Iodine in specific combination as Thyroglobulin.

"Inkretan" tablets are standardised by the gaseous metabolism method—therefore constant in action.

Prof. Carl von Noorden reports:

"For specific reasons preference is given to 'Inkretan' tablets, which are standardised by the Iodine content. They permit of easy graduation of the effective dose, and in suitable cases show good powers of activity."

Special Literature supplied on request, with summary of treatment and suggestions as to diet.

"Inkretan" tablets are supplied in bottles, each 25 or 50. A bottle will be sent free on request.

Calcium Deficiency in Expectant & Nursing Mothers

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to ensure adequate calcium retention.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

calcium-sodium-lactate

Also supplied *direct* for Doctor's own dispensing at 15/- per 1000 plain tablets.

May we have the pleasure of sending you samples in order that you can appraise the merits of Humanised Trufood?

TRUFOOD LTD., THE CREAMERIES, WRENBURY, NR. NANTWICH, CHESHIRE.

INFLUENZA

AS the nose and throat in this disease are the only routes of infection, it follows that the organism should be easily destroyed or attenuated by an insufflation powder of high bactericidal value. This is now readily available in the form of Dimol Snuff.

This Snuff is guaranteed to be equal in bactericidal value to 30 per cent. pure carbolic acid and to be perfectly free from all deleterious action on the mucosa. As a prophylactic measure the use of this powerful non-toxic powder is clearly indicated.

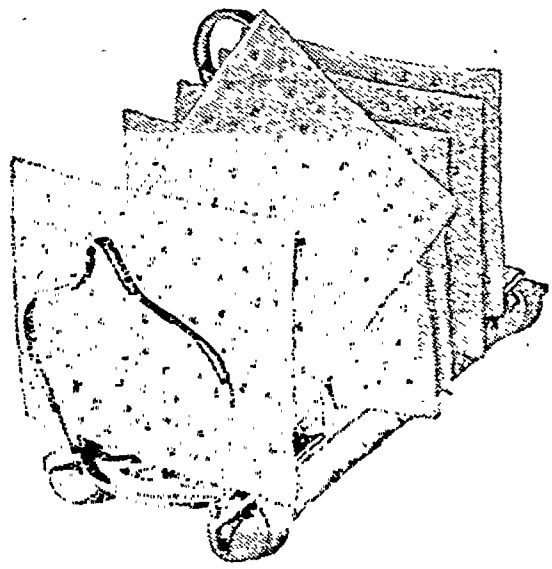
Common Colds, Nasal Catarrh, etc.

A nose and throat specialist of 30 years' experience who has been prescribing Dimol Snuff for over three years in the disinfection of the nares and nasopharynx, writes:

"The discomforts of nasal catarrh are known to everybody, especially in the fluctuating temperatures of an English winter: but there is no reason why any type of this common ailment should not be dealt with promptly and (1) aborted in its incipient stages, (2) ameliorated in its active stages, and (3) quickly cured, with the aid of Dimol Snuff. . . ."

"This Snuff, taken three or four times a day during an epidemic of influenza, should be a perfect and pleasant preventive to the insidious settlement of the pervading bacillus in the nose and throat."

DIMOL LABORATORIES LIMITED, 40, Ludgate Hill, London, E.C.4.



Vita-Weat prescribed in place of ordinary bread

A most agreeable and beneficial alternative to soft wholemeal or white bread, especially in cases where *a diet regime is prescribed, is to be found in* Vita-Weat, the British whole-wheat crispbread.

Vita-Weat presents the whole-wheat berry in a concentrated and digestible form, with the vitamins A, D, and B in an active condition.

The "Practitioner," reporting on Vita-Weat in August, 1927, said: "The value of this crispbread is not only in the vitamins it contains, but because it requires thorough mastication, while the branny scales serve as a corrective to intestinal inertia."

The "Lancet," in its report on June 11th, 1927, vouched for Vita-Weat in the following terms: "It will be noted that the caloric value is high." (The "Lancet's" own calculation was 1,846 per lb.) . . . "it has a pleasant texture and flavour. . . . It is undoubtedly a valuable foodstuff, more particularly in respect of its content of vitamin B."

The Royal Institute of Public Health report, printed in the "Journal of State Medicine," Vol. XXXV, No. 8, stated that "Vita-Weat crispbread contains all the necessary elements and possesses a good physiological fuel value." and further said that the special method of manufacture "gelatinises the starch grains and thoroughly disintegrates the cellulose, fibre, etc., of the grains, thereby rendering the finished product completely assimilable."

These valuable testimonials show that the regular use of Vita-Weat will promote health, vigour, and physical fitness.

The Original and Standard
Emulsion of Petroleum

Angier's Emulsion

is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

Influenza and Sequelæ.

The unique soothing properties of Angier's Emulsion and its favourable influence upon assimilation and nutrition make it eminently useful both during and after influenza. It has proved most efficacious in relieving the catarrhal symptoms, whether tonsillar, bronchial, or intestinal; also in combating the nervous depression and debility. After the attack, or when the patient's nutrition and vitality are at the lowest ebb, try the continued use of Angier's Emulsion for convincing proof of its effects as a tonic and restorative.

Bronchitis, Sub-Acute and Chronic.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases.

In Gastro-intestinal Disorders

of a catarrhal, fermentative, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. It exercises sedative, demulcent, lubricant effects throughout the entire intestinal canal, and it restores tone to all the digestive functions Moreover, it offers the very best vehicle for the administration of astringents and antiseptics (bismuth, salol, &c.) The Emulsion may be administered undiluted or in any desired vehicle.

The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

TRADE MARK "TABLOID" BRAND TONICS

The medicament is untasted. An additional advantage is that business patients find the little bottle convenient to carry to the office—it is easily slipped into the pocket or handbag.

"TABLOID" GLYCEROPHOSPHATES COMPOUND

Sugar-coated—bottles of 25 and 100

Equivalent to 1/2 dr. of Syrup, 1/3 and 3/9

"TABLOID" HYPOPHOSPHITES COMPOUND

Plain or sugar-coated—bottles of 25 and 100

gr. 1½ = ½ dr. of Syrup, 8d. and 2/-
gr. 3 = 1 dr. „ „ 1/- „ 3/-

"TABLOID" ARSENICAL COMPOUND

Contains Arsenious Acid, gr. 1/100; Exsiccated Iron Sulphate, gr. 1; Calcium Sulphide, gr. 1/4; and Extract of Gentian, gr. 2

Sugar-coated—bottles of 100, 1/9

"TABLOID" EASTON SYRUP

Sugar-coated—bottles of 25 and 100

Equivalent to ½ dr. of Syrup, 10d. and 2/6
„ „ 1 dr. „ „ 1/3 „ 3/9

The examples above are selected from the full list in *Wellcome's Medical Diary*

INTERESTING ARCHÆOLOGICAL REMAINS OF THE EARLY PIONEERS OF JAPAN.—From the contents of the tumuli, in which they were buried, some idea can be gained of the culture of the rovers who left the mainland of Asia for the islands of Japan. The most interesting and characteristic among these objects is the *magatama* or "curved jewel." This seems to have been their most common amulet, and article of personal adornment. It was made of the semi-precious stones and was held in the highest esteem; indeed, it now forms, with the sword and mirror, part of the insignia of Japan. The collar, composed of jaspar nephrite, and here reproduced, has the "magatama" in prominent positions; other examples are shown within the collar.

CAREL A. HOEFFTCKE

7, Harley Street, London, W.1.

Inventor and Maker of Hoefftcke's Extension Appliance.

The benefits of my Ambulatory Extension Treatment have been described by many eminent medical men in cases of tubercular diseases of hip, knee, and ankle joints, fractures of the long bones, especially neck of femur fractures, and cases of Osteo-Arthritis of the hip and those of Rheumatoid origin of knee and ankle.

The main advantage of the use of the extension appliance for those cases is that the patient is enabled to walk about and lead an active life while extension is maintained between the fragments of the fractures and between the articulating surfaces in diseased joints. By means of active movement the circulation of the parts is not restricted as in the recumbent treatment.

Union of fractures, even in the so-called un-united fractures, has been greatly assisted by active movement, and subsequent improved circulation of the blood.

In those of the arthritic conditions, cases have been described where inflammatory changes in the articulating surfaces have been restored to the normal with complete active movement as a result.

Some of the hospital cases of tubercular joint diseases were treated while the patients lived in the poor districts of London, and still good results were obtained.

In many of the Rheumatoidal cases, especially where knees were contracted, the first part of the treatment had to be carried out in the home of the patient, owing to the impossibility of the patient being moved, due to the pain in the joints.

A great improvement in most of the cases was obtained if the patients were able to convalesce in certain parts of the country. My experience has taught me that sea air, especially on the East Coast, is detrimental to the extension treatment of Rheumatoid Arthritic cases, hilly and mountainous districts always exerting a more beneficial action on the diseased joint.

For about twenty years I have suggested to the surgeons and physicians who have sent me their cases that they should advise their patients in the convalescent stage to spend a certain time in a place called Trefriw, in North Wales. The valley of the Conway enjoys a climate very much the same as that of the south of France, and statistics show that in Trefriw the temperature in winter is much higher and the yearly rainfall much less than in London.

In addition to the beautiful mountain air, the patients are able to derive great benefit from the strong Ferrous Sulphate waters obtainable at Trefriw.

In order that I may carry out my treatment under the supervision of medical men who send me their cases, and, if necessary, of a visiting physician, a number of my friends and I have formed a private limited company—Ambulatory Treatment, Ltd.—which has taken over the Bellvue Hotel at Trefriw. This hotel is now being altered and reconstructed to fulfil the requirements necessary for the ambulatory treatment.

Any inquiries should be addressed to 7, Harley Street, London, W.1.

A British Medical Association Lecture

ON THE

RELATION OF EARLY MISTAKES IN INFANT FEEDING TO THE DYSPEPSIAS OF LATER INFANCY AND CHILDHOOD.*

BY

ERIC PRITCHARD, M.A., M.D., F.R.C.P.,

MEDICAL DIRECTOR, THE INFANTS HOSPITAL, VINCENT SQUARE, WESTMINSTER.

At a recent meeting of the Section for the Study of the Diseases of Children at the Royal Society of Medicine, Dr. Jules Taillens,[1] professor of paediatrics at the University of Lausanne, gave a very interesting address on the same subject as that which I have chosen for this lecture—that is to say, "The dyspepsias of childhood."

Professor Taillens claimed that these dyspepsias often took a misleading form and produced symptoms of general weakness, wasting, pyrexia, and even coughing, which were frequently mistaken for those of tuberculosis. He further stated that gastric hyperchloracidity, or, as we usually call it, hyperchlorhydria, was the most frequent cause of these dyspepsias. Owing to the limitation of time, Professor Taillens did not explain exactly how hyperchlorhydria developed into the above group of symptoms, and although I agree with him that hyperchlorhydria may ultimately produce such results, I am not sure that I should agree with him as regards the explanation. His address, however, created so much interest that I thought that the same subject might well form the basis of this lecture.

If hyperchlorhydria, or the excessive secretion of hydrochloric acid in the stomach, is accompanied by a corresponding supply of pepsin, there must be a great capacity for digesting protein, and, as a matter of fact, there is usually in cases of hyperchlorhydria a considerable appetite or craving for nitrogenous foods. Individuals who are the subjects of such gastric hyperacidity do not, as far as my experience goes, suffer at first from any of the recognized symptoms of dyspepsia. They are usually, at least during the early years of life, individuals with a healthy appetite. They enjoy their food, are impatient for their meals, and appear to be well nourished. They sometimes feel a so-called "sinking of the stomach" if their cravings for food are not immediately satisfied, but these discomforts pass off rapidly after a meal. Such individuals deserve to be regarded as "eupeptics" rather than dyspeptics. None the less, if these individuals, as they grow older, continue with full meals, they begin to have epigastric pain about two hours after food—a premonition of duodenal ulcer. Similarly, infants and quite young children with various degrees of hyperchlorhydria do not suffer from ordinary dyspeptic symptoms, but they do suffer from periodic attacks which, according to my own interpretation, depend on a disturbance of liver function. Among the several functions which the liver performs, one of the chief is the de-aminization of amino-acids, and their conversion into urea or ammonia. There is a limit to the tolerance of all organs with respect to each of their functions, and when these limits of tolerance are overstepped they will show signs of fatigue and cause the development of various symptoms which are the direct result of such breakdowns; the liver is no exception to this rule—with overwork its power to de-aminize amino-acids begins to wane.

Now with hyperchlorhydria there are strong inducements to consume excessive quantities of protein foods, which, if indulged, will impose on the liver the duty of de-aminizing very large quantities of amino-acids. The result is easy to predict. When hepatic function fails and the de-aminizing process is feebly conducted, it follows that the amino-acids in an unchanged condition will gain access to the systemic circulation.

In a very interesting paper[2] contributed by Dr. H. W. Barber and Dr. G. H. Oriel to the Section of Dermatology at the Annual Meeting of the British Medical Association held at Cardiff, the results of such flooding of the blood with amino-acids were described as an asthma-prurigo symptom-complex. The group of symptoms described by these authors is made up of:

1. Cutaneous symptoms of the urticarial type.
2. Subcutaneous symptoms of the nature of angioneurotic oedema.
3. Respiratory symptoms of the asthmatic type.
4. Gastro-intestinal symptoms representing certain forms of vomiting and diarrhoea.
5. Nervous symptoms, including migraine and epilepsy.
6. Articular symptoms, including paroxysmal hydrarthrosis.

All these symptoms are, of course, never found combined in any one person suffering from excess of amino-acids in the blood. In infants and young children the symptoms are of rather a specialized form, but the point which I wish to emphasize is, that there are a large number of symptoms in children which follow as a result of the condition of hyperchlorhydria which cannot properly be classified as dyspeptic symptoms, but rather as those of liver inefficiency, and associated with an increase of amino-acids in the blood. I venture, therefore, once more to suggest that many or most of the results of hyperchlorhydria are due to too active a digestion rather than to a bad one.

Before I leave this subject I would like to say a few words with respect to the etiology of the very common condition of hyperchlorhydria in young children. It arises as a natural result of the modern practice of feeding infants with cow's milk with an excessive content of caseinogen, and it matters very little whether the milk is ordinary dairy milk or dried milk, for in both cases it is almost invariably given in a way which calls for a high degree of gastric acidity, owing to its considerable protein concentration.

Breast milk, or rather its protein content, can be digested by pepsin when comparatively little acid is secreted in the stomach, owing to its low buffering capacity, whereas cow's milk requires the addition of a large amount of acid, owing to the high buffer effect of its proteins and phosphates. Hence it follows that if infants can be fed on cow's milk without the development of vomiting and other gastric symptoms the amount of acid secreted must be very great, much greater than would have been the case if breast milk alone had composed their diet. Now, owing to various resources, such as the addition of sodium citrate to such milk dilutions (which prevents the coagulation of casein in a heavy clot with consequent vomiting), gastric tolerance can usually be acquired by infants, even though the milk is only slightly diluted or not diluted at all. This tolerance, with its natural concomitants hyperchlorhydria and a large appetite for protein foods, leads to overfeeding, overfeeding leads to overproduction of amino-acid bodies, and these in turn to hepatic failure and to a flooding of the system with unaltered amino-acids—hence the appearance of symptoms belonging to the "asthma-prurigo" syndrome.

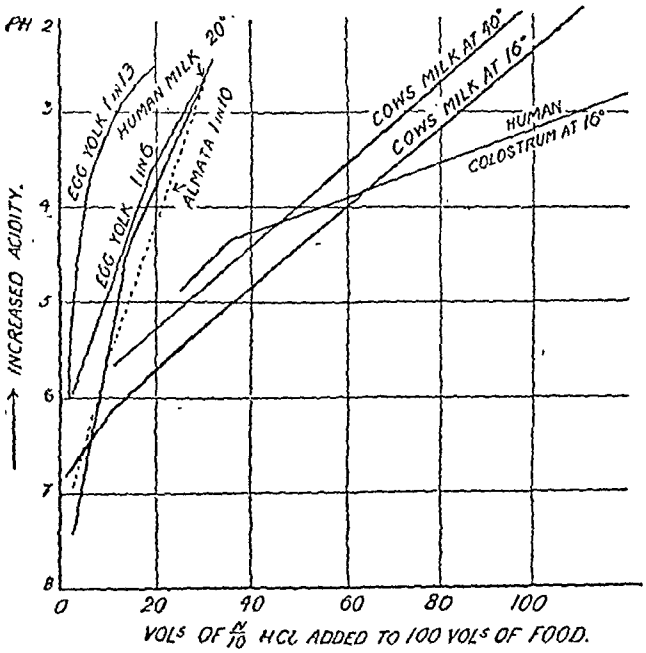
I do not wish to complicate the subject with unnecessary detail, but the accompanying graph, which has been constructed for me from figures supplied by Mr. Leslie J. Harris, D.Sc., working in the Nutritional Laboratory at Cambridge, and confirmed by Dr. Montague Maizels, working in our own laboratory at the Infants Hospital, shows the amount of acid which it is necessary to add to breast milk and cow's milk respectively to bring them up to the degree of acidity at which pepsin will effect the digestion of the protein.

From this graph it will be seen that while about 24 c.cm. of decinormal hydrochloric acid must be added to 100 c.cm. of breast milk to activate the pepsin and make it effective, between 40 c.cm. and 60 c.cm. must be added to cow's milk to obtain the same result. This difference is due to the high buffering effect of the cow's milk. From this it is clear that if an infant is fed on cow's milk instead of breast milk the acid-secreting cells of the gastric mucous membrane will tend to be more highly developed than in the case of breast-feeding, and a state of hyperchlorhydria will result, which will give an appetite for protein foods and cause the condition to "grow worse by what it feeds on."

Mr. Leslie Harris tells me that the buffer value of different foodstuffs may generally be represented with fair accuracy in the ratio of their protein content—that is to

* Delivered before the Cardiff Division, December 20th, 1928.

say, it makes very little difference what be the source of the protein, the actual amount of acid which must be secreted to digest it will be proportional to the actual quantity of protein present in the food. Hence cow's milk, with its high protein content and consequently high buffer value, will necessitate the secretion of large quantities of



In this graph the vertical line is graduated in accordance with its *p*H or degree of acidity: *p*H 7 is neutral point; 6, 5, 4, 3, and 2 represent respectively increasing degrees of acidity. The degree of acidity at which pepsin digestion is at its maximum is about 3 *p*H, although it begins at a lower point—that is, about 4 *p*H. The horizontal line marked 0, 20, 40, 60, 80, 100 indicates the volumes of decinormal (N/10) HCl added to every 100 volumes of food.

acid in the stomach, and will lead ultimately to a condition of hyperchlorhydria.

I hope it will not be assumed that I attach little importance to the dyspepsias which result from a deficient secretion of hydrochloric acid, owing to the fact that I have given special prominence to the condition of hyperchlorhydria.

One of the most important lessons I have learned from certain investigations[3] which we have made at the Infants Hospital is that the *p*H of gastric juice in infants shows an immediate fall with the onset of pyrexial and other constitutional symptoms. With a falling off in efficiency of gastric digestion, followed in all probability by similar falls in the efficiency in pancreatic and intestinal digestion, there results a considerable danger of undigested food entering the large intestine, which gives opportunity there for bacterial decompositions. Under normal conditions neither decompositions nor fermentations occur to any appreciable extent in the small intestine, for although the chyme in this part of the bowel is not absolutely sterile, it is so relatively, owing to the antiseptic influence of the acid gastric juice. Under conditions of hypochlorhydria the stomach does not exercise the same influence, and the chyme when it enters the small intestine is in a less sterile condition, and consequently more liable to fermentative and decomposition changes. Hence a condition of hypo-acidity in the stomach has a tendency to lead later to intestinal toxaemia.

Now although the poisonous products of decompositions and fermentations in the large and small bowel may lead to local disturbances, such as catarrhal enteritis, diarrhoea, colic, or flatulence, the more serious effects are, as in the case of hyperchlorhydria, remote and constitutional. The toxic products of such decompositions are absorbed and carried along the portal channels to the liver, where under normal conditions they are detoxicated and rendered harmless, in a manner comparable to the de-aminization which occurs in the liver in the case of the normal products of protein digestion. In the same way that the liver can fail in its de-aminizing functions from overwork, so also can it fail in its detoxicating functions with respect to the poisonous products which result from bacterial activity in the bowel.

Now when the liver fails in its detoxicating functions the unaltered toxins enter the systemic circulation and exercise their deleterious influences on the body as a whole, and on the cells of the central nervous system in particular. The symptoms of this condition are, therefore, largely nervous, and were it not that the resulting crises are accompanied by anorexia and vomiting, which preclude the further taking of food, the symptoms would be continued indefinitely until death terminated the scene. Thus we see that, both in hyperchlorhydria and hypochlorhydria, the symptoms are remote and not directly concerned with the function of the digestive system proper.

The primary symptoms associated with dyspepsia are vomiting, gastric pains, colic, wind, diarrhoea, and constipation—symptoms which represent disturbances of the motor and not the digestive functions of the alimentary tract. Almost without exception, however, motor symptoms are combined with the deferred constitutional symptoms. In infants it is the motor symptoms which mainly attract attention, whereas in older children and grown-up individuals the main symptoms are of the deferred constitutional type.

Types of Dyspepsia in Infancy and Early Childhood.

In the time at my disposal it would obviously be impossible to give any detailed account of all the common varieties of dyspepsia, nor, indeed, do I feel competent to classify them on any rational or comprehensive basis, but I think if I take certain representative types which in my experience are the most frequently met with in infancy and early childhood, I shall be able to give certain indications for the recognition of the many combinations of them with which we are often perplexed. The three types that I propose to take are as follows:

1. Vomiting, which occurs in infancy, and is due to over-action of the pylorus.
2. The coeliac type of diarrhoea, generally found in children between 1 and 6 years of age.
3. The chronic dyspepsias of early childhood (3 to 7 years), accompanied by periodic attacks of vomiting with acidosis (cyclic vomiting).

Type 1.

A considerable number of the infants under 3 months of age who are brought to the Infants Hospital for so-called *indigestion* have a history of vomiting suggestive of pyloric stenosis, and in quite a large proportion of such cases a diagnosis to this effect has already been made by the practitioner or welfare centre sending up the case. Although the surgical treatment by Ramnstedt's operation is a most satisfactory and rapid means of alleviating the pyloric obstruction, I never refer such cases to the surgeon unless the symptoms refuse to yield to ordinary medical measures. The presence of a palpable tumour with visible peristalsis, even when these symptoms are combined with a history of intractable vomiting, is not, in my opinion, sufficient evidence of pyloric stenosis to justify an operation without further corroboration. I have had many cases with these symptoms in which the *x*-ray examination after a bismuth meal has revealed rapid emptying of the stomach through the pyloric opening. In such cases, however, obstinate constipation is not one of the symptoms, as it is in true pyloric stenosis, and there is usually faecal matter as well as mucus in the motions. A bismuth meal is of the greatest help in distinguishing pyloric stenosis from simple overaction of the motor functions of the stomach, but I have known a bismuth meal pass quite normally through the pylorus and yet ordinary food be retained in the stomach until it is finally evacuated by vomiting. I regard lavage of the stomach some three hours after a feed as giving better evidence of the degree of motor efficiency of the stomach, or at least of the capacity of the stomach to empty itself, than a bismuth meal, although both, taken in combination, give still more reliable evidence. A wash-out of the stomach three hours after a meal will throw light on several points—the character and quantity of the residue, its degree of acidity or alkalinity, and the actual volumetric capacity of the stomach itself.

All these items of evidence pieced together are of great assistance in diagnosing the cause of the vomiting, and

in formulating an opinion as to whether medical or surgical means are indicated in the treatment.

In the vast majority of cases of vomiting in young infants investigated on these lines it is found unnecessary to have resort to surgical intervention. The cause is nearly always spasm and not true stenosis of the pylorus. This spasm almost invariably yields to ordinary medical treatment and appropriate feeding. Now I am sure I am not exaggerating when I say that in 99 per cent. of cases of persistent vomiting in young infants I have found a history of gross errors in feeding during the first few days or weeks of life, which has adequately and satisfactorily accounted for the setting up of pyloric spasm. There is almost invariably a history of overfeeding in cases of breast-fed infants, and of unsuitable feeding in the case of those artificially fed.

Spasm is very easily set up in the sensitive pyloric sphincter, the true function of which is to protect the delicate intestinal tract from unsuitable varieties or quantities of food. Spasm once set up in this sphincter during the early days of life, when it is learning its functions, is very apt to persist and continue even though unsuitable food is no longer to blame. A well-organized pyloric reflex—a reflex which protects the intestines from excessive quantities of semi-digested products, or from the irritation of totally undigested food—is one of the essential conditions of a good intestinal digestion. This pyloric reflex can be so disorganized by early mistakes in feeding that re-education may become difficult or impossible, and symptoms of dyspepsia persist during the whole of life.

Excessive acidity, or hyperchlorhydria, sometimes delays the emptying of the stomach, and when this occurs long-continued contractions of the pyloric muscles may lead to their hypertrophy. On somewhat comparable grounds subacidity of the gastric juice also leads to delayed emptying and long-continued contraction of the pylorus and hypertrophy. Inasmuch as the pH of the stomach is mainly dependent on the nature of the food, as previously explained, we see, too, how to a great extent the establishment of a normal pyloric reflex, and all that this portends, is dependent on a correct adaptation of the food to the physiological requirements.

Now let me state quite briefly how all the troubles which depend on a perverted pyloric reflex can be avoided. In breast-feeding the first secret is to regulate the quantity of milk which enters the stomach during the early days of life by the invariable employment of the "test" feed, a control which is particularly necessary when lactation is first established and when there are great dangers of flooding the stomach with an excess of milk.

In artificial feeding the desideratum is never to allow any variety of food to gain access to the stomach which can provoke any exaggerated or excessive gastric or pyloric reaction. The worst offender of all is cow's milk, no matter what be the degree of dilution. Personally I always use as the basis for the artificial feeding of newborn babies very thoroughly peptonized milk modifications. If this precaution is taken and the proper quantities are given at regular intervals, I guarantee that a case of so-called hypertrophic pyloric stenosis will never be met with; indeed, I will go so far as to assert that there will be no case of persistent vomiting of any kind.

I am often asked what is the ultimate fate of these so-called pyloric cases. As far as my experience goes, their fate depends on the degree of aggravation which has in the first instance brought about the spasm of the sphincter. Cases in which only slight defects in the feeding have produced spasm of the pylorus necessitating operation usually do badly, because a violent reaction to a slight degree of stimulation implies a very sensitive or spasmophilic state of the nervous system. I have noticed in such cases a general tendency in later life to increased sensibility to all forms of injurious agents—a sort of general anaphylaxis. Cases in which very gross liberties have been taken with the feeding during the early days of life, without producing very violent reaction—that is to say, reactions which are easily controlled by simple medical measures without resort to operation—usually do extremely well as soon as the vomiting ceases.

Type 2.

Now with respect to the "coeliac" type of dyspepsia, I will preface my remarks by saying that I do not regard the syndrome to which this name has been applied as a clinical entity or definite disease. I regard it merely as a combination of symptoms resulting from a variety of causes, mainly concerned, however, with an atrophic condition of the intestinal mucosa and atony of the intestinal walls, but sometimes due to an atrophic or undeveloped condition of the pancreas. The liver is certainly small in many of these cases, but this is better explained on the ground that the liver has little work to do owing to restricted absorption, than that it is small owing to innate or congenital causes. Moreover, the fact that this smallness of the liver itself disappears as recovery takes place also militates against the view that there is any congenital defect in the liver itself, or that coeliac disease itself is of congenital origin.

In nearly all cases of "coeliac" disease which have come under my notice there has been a history of good or normal progress up to a certain point, and that then there has been a crisis of some kind with diarrhœa and all the usual symptoms. Moreover, in the majority of these cases there has been a history of bad feeding—generally excess in the total quantity combined with deficiency of vitamins, which will explain all the subsequent events. But in whatever way these cases commence, there can be no doubt that if an atrophic and unhealthy condition of the intestinal mucous membrane exists, it can be perpetuated and aggravated by the treatment to which nearly all "coeliac" cases are subjected. Owing to the peculiar character of the stools, fats are almost universally eliminated from the diet, and consequently there is almost complete starvation as regards fat-soluble vitamins as well as fat itself; secondly, the consumption of fruit is vetoed because of the diarrhœa; and thirdly, vegetables and other [illegible] foods are forbidden because of their [illegible] peristaltic action. So-called "coeliac" disease, or at least a very large proportion of the cases which pass under this name, are associated with, if they are not definitely due to, dilated and atrophied intestines, and these two latter conditions are almost certainly caused by bad feeding, and very probably chiefly by want of vitamins. If this is so, no course of treatment could be worse than the one outlined above. It illustrates the therapeutic principle of "treating a bite with a hair of the dog that bit"—that is to say, a bad dietary is treated by a worse one. I find these cases always improve and generally become cured by acting on the principle that since little food can be absorbed little food must be given; and since the cause of the disease is mainly a want of correct balance in the dietary, the diet must be properly balanced, and contain a good representation of vitamins and mineral elements.

The presence of fat in the stools is no contraindication for the giving of fats. Fats in the form of insoluble soaps furnish, in the case of infants, their only source of roughage, and they serve the same purpose at any time of life. But in order that insoluble soaps may be formed out of the neutral fats consumed as food two conditions must be fulfilled. First, the fats must be "split," and secondly, there must be an adequate supply of calcium or magnesium with which the fatty acids can combine to form the insoluble soaps. Hence the stools of "coeliac" patients should be examined to see whether soaps are present or not. If either fatty acids or soaps are present it proves that the fats consumed are split, or digested, and that lipases are provided by the pancreas or other source. If only, or mainly, neutral fats are present in the stools, pancreatic preparations must be given independently to ensure the splitting of the fat, and in all cases a liberal supply of calcium should be provided to neutralize the fatty acids and so form insoluble soaps. For this purpose either prepared chalk or aromatic chalk powder must be given in full amount. One of the chief essentials in the treatment of these cases is unlimited patience and rigid adherence to the main principles in spite of obvious temptations. The dangerous time is when improvement begins to take place and appetite returns, for then there are strong inducements to relax rules and increase quantities. Since in

these cases little food can be absorbed; such sources of energy as are available must be conserved by keeping the patient thoroughly warm—in bed for preference—and by limiting exercise as far as possible.

The ultimate fate of the majority of "coeliac" cases is recovery, but even after what may be regarded as complete recovery there is always a tendency to recidivism, and some dilatation of the intestines usually persists.

Type 3.

As I have already indicated, the symptoms of certain forms of dyspepsia are so remote and general that they are liable to be attributed to tuberculosis or other constitutional trouble, rather than to actual defects in the digestive processes. The kind of case which I am about to describe is essentially of this character in its most typical form. It occurs in children between 2 and 16 years of age. It is chronic and remittent in character.

Children suffering from this form of dyspepsia are never really well, neither do they look well. They usually do not complain of feeling ill, but they have little energy, are easily tired, and have capricious appetites. There is often a continued temperature, usually under 100° F., sometimes lasting for many months. The complexion is sallow, with dark rims to the eyes, the tongue is dirty, and the breath tainted. There is irritability of temper, restlessness at night, or night terrors. The children often complain of abdominal pain or stitch in the side on running. The urine is usually thick, cloudy, or ammoniacal, and the stools are offensive. One of the most diagnostic and characteristic of the symptoms is the regular manner in which periodic attacks of biliousness supervene. These symptoms make up a clinical picture which must be perfectly familiar to everyone; but since all of them in combination never occur in one case the presence of even a few of them should put the practitioner on his guard.

All these symptoms can be rationally and satisfactorily explained on the assumption that the food consumed is not completely digested, owing either to its quality or total quantity, or to the relatively deficient powers of the digestive functions to cope with the task imposed upon them. Whatever may be the cause bringing about this failure of digestion the result is the same. Food which should have been digested normally by the normal enzymes of the alimentary tract remains undigested, or only partially digested, and becomes the pabulum of bacteria in the large bowel, and, as a consequence, the colon assumes an unhealthy condition, with offensive stools, flatulence, abdominal pains, and stitch in the side. This stitch in the side, so very characteristic of intestinal toxaemia, is, I believe, caused by the dragging of a heavy and sagging colon on its two points of support—its hepatic and splenic flexures—a dragging which is intensified by exercise in the upright position.

The toxic products of intestinal putrefaction are absorbed and carried to the liver, where for a time they may be effectually dealt with and rendered innocuous. Failure, however, is evidenced by offensive breath, dirty tongue, irritability, and other nervous symptoms. After varying periods of endurance the liver breaks down in function, and then the systemic circulation is inundated with a flood of unaltered toxic products, with intensification of the nervous symptoms, which take the form of vomiting, high temperature, migraine, or sick headache.

Under these conditions, and especially owing to the vomiting, the further consumption of food becomes impossible, and the liver obtains a much-needed rest. General recovery then takes place, the appetite returns, and the whole cycle of events is repeated with systematic regularity. The treatment of these bilious attacks, or cyclic crises, is usually by calomel or grey powder. This treatment, which as a rule gives immediately good results, is not really rational or far-seeing, for its efficacy is mainly due to stimulation of the liver, and not to removal of the cause. It acts, in fact, on the principle of "spurring on the tired horse," instead of taking the load off its back. The toxic bodies which directly bring about these breakdowns of liver function are due to the decomposition of nitrogenous foods, such as butcher's meat, fish, eggs, poultry, and milk. Hence it is obvious that the treatment should be concerned with a limitation of the intake of these particular foods. On the other hand, the fermentations which take place in carbohydrate and cereal foods lead to the formation of considerable quantities of acid bodies, such as acetic acid, butyric acid, lactic acid, propionic acid, and so on; these do not seriously tax hepatic function after absorption, but they do seriously drain the bicarbonate reserves of the blood and lead to those true conditions of acidosis which so often complicate the actual hepatic crisis. It should be clearly recognized that conditions of acidosis proper, in which there is a reduction of the alkaline reserves of the blood, should be distinguished from conditions of ketosis in which there is usually acetone in the blood, the breath, and the urine. A true ketosis seems to be one of the results of defective fat metabolism and hepatic insufficiency, and therefore it is scarcely to be wondered at that in these cases of periodic liver attacks due to intestinal toxaemia the condition should be complicated by a ketosis. In fact, I think it may be assumed with some confidence that in cases of intestinal toxaemia due to defective digestive processes there is generally a combination of all these conditions—hepatic crisis, ketosis, and true acidosis. The rational treatment of these cases involves three main principles of therapeusis: First, and mainly, the limitation of nitrogenous foods. Secondly, the limitation of all foods within the bounds of physiological requirements. Thirdly, the prevention as far as possible of intestinal decomposition by sterilization of the intestinal tract. Finally, by the prevention of conditions of true acidosis by the free administration of alkalines.

I hope that the three types which I have chosen to illustrate my thesis will help to show that if the digestive functions are imperfectly performed certain immediate, and, if I may use the term, proximal, symptoms, are liable to be produced which are mainly concerned with disturbances of the neuromuscular mechanisms that control the transit of food through the alimentary tract. These symptoms carry a warning note which, if attended to, should obviate the development of other, more serious and more distal, symptoms connected with the breakdown of liver function and with the poisoning of the system with various toxic substances.

THE SIGNIFICANCE OF INTRADERMAL TUBERCULIN TESTS.

A PRELIMINARY NOTE ON AN INVESTIGATION IN PROGRESS BY THE MEDICAL STAFF OF THE WELSH NATIONAL MEMORIAL ASSOCIATION.

BY

PROFESSOR S. LYLE CUMMINS, C.B., C.M.G., M.D.,
DIRECTOR OF RESEARCH, WELSH NATIONAL MEMORIAL ASSOCIATION.

THE intradermal method of tuberculin testing was introduced by Mendel[1] and Mantoux[2] in 1908. For quantitative tests it has the advantage over the von Pirquet reaction in that the whole of the tuberculin used does actually enter the tissues. Happ and Casparis[3] consider that 0.01 mg. of tuberculin given intradermally corresponds to the usual von Pirquet test. While the von Pirquet test carried out according to the technique described by me in the *British Medical Journal* of February 2nd, 1924, appears to give results equivalent at least to 0.1 mg. of tuberculin intradermally, there can be no question but that the intradermal method is a much more sensitive test than the cutaneous one, and gives a greater amplitude in the elicitation of latent infection.

As compared with the subcutaneous tuberculin test, the intradermal method aims at a local, not a general, reaction, and it is an interesting fact that doses of tuberculin capable of giving rise to severe focal and constitutional reactions in infected persons can be given intradermally without exciting any appreciable response other than the local one at the site of inoculation. An excellent account of this and other forms of the tuberculin test was given by Burhans[1] in 1927, and should be consulted by all interested in the subject.

At a meeting of the medical staff of the Welsh National Memorial Association in December, 1927, it was decided to test out the intradermal method on various types of tuberculous patients with a view to arriving at a clearer idea of its significance in relation to the disease. As director of research to the association it has fallen to my lot to draw up a scheme of investigation, co-ordinate the work, and analyse the results; but nearly all the actual tests have been carried out by my colleagues of the medical staff of the association, and in particular by Drs. D. W. Fenwick Jones, D. H. Mills, and L. R. Clark; and for all this help I desire to express my gratitude. I also wish to thank Dr. R. A. O'Brien, director of the Wellcome Physiological Research Laboratories, through whose kindness a very reliable sample of old tuberculin (O.T. No. 1154, B. W. and Co.) was made available for use in all the tests now recorded. This tuberculin was put up by me in the following strengths, and supplied, as required, to the medical staff: 1 in 10,000, 1 in 5,000, 1 in 1,000, and 1 in 500. The diluent used was sterile normal salt solution to which 0.5 per cent. of carbolic acid was added. Medical officers were warned that diluted tuberculin is liable to deteriorate, and that the phials should be regarded as unreliable three weeks after the date of issue. The inoculations were given intradermally, a volume of approximately 0.1 c.cm. of the appropriate dilution being injected by means of a whole-glass hypodermic syringe with a very fine accurately fitting needle. It was found that needle No. 214, B. W. and Co., was suitable for the purpose. Special precautions were taken to avoid too deep a puncture. The escape of tuberculin into the subcutaneous areolar tissue vitiates the test and exposes the patient to the risk of a general reaction. The site chosen was usually the outer surface of the arm a few inches below or above the elbow-joint. No injection was considered satisfactory if it did not raise a circumscribed wheal at the point of inoculation. It was decided not to give "control" injections of sterile diluting fluid, though these are advocated by Burhans.

The number of inoculations to which patients will submit is limited, and it is my experience that "reactions" after such control inoculations are so very rare as to be practically negligible. In the majority of cases a positive reaction with any given "dilution" was accepted as a proof that the patient concerned would be positive with the stronger preparations—that is, a patient reacting to 1 in 10,000 was assumed to be positive also to 1 in 5,000, 1 in 1,000, and 1 in 500. That this assumption, which underlies the percentages in the following records, is correct, was proved by the results in those few patients to whom all four strengths were given. In these it was found that the intensity of the reaction increased regularly with each increase in strength of tuberculin.

Comparison of Reaction in Healthy Adults and Tuberculous Patients.

A group of 46 healthy male adults residing in London was tested by me according to the technique above described except that only two dilutions of tuberculin—1 in 5,000 and 1 in 1,000—could be used. To these healthy volunteers, who desire to remain nameless, my sincere thanks are due. The results in this healthy group were compared with the results in 150 tuberculous patients, a miscellaneous group including adults and children, males and females, pulmonary and non-pulmonary, under treatment by the association. The findings are compared in Table I.

TABLE I.—*Tuberculin Reactions in the Healthy and the Tuberculous.*

Tuberculin Dilutions.	Percentages Positive.		Average Size of Reaction in Centimetres.*	
	Healthy.	Tuberculous.	Healthy.	Tuberculous.
1 in 10,000	80	37	1.30	0.5
1 in 5,000		61		1.0
1 in 1,000	93	70	2.07	1.4
1 in 500		74		1.6

* All the reactions in the "healthy" group, but only 37 reactions in the tuberculous group, were measured.

It will be apparent from the above table that, both in the percentages of positives and in the extent of the raised area of reaction, the healthy persons gave results over 20 per cent. higher than the persons actually suffering from tuberculosis. This finding raised the question of the relation, if any, of tuberculin sensitivity to the severity of the disease; and the above miscellaneous group of patients was now analysed according to clinical type.

Comparison of Pulmonary and Non-pulmonary Cases.

Pulmonary tuberculosis is, on the whole, more severe than non-pulmonary tuberculosis; so a comparison was made between 64 pulmonary and 83 non-pulmonary patients, the latter constituted, for the most part, of cases of bone and joint tuberculosis.

TABLE II.—*Tuberculin Reactions in Pulmonary and Non-pulmonary Cases.*

Tuberculin Dilutions	Percentages Positive.		Average Size of Reaction in Centimetres.*	
	Pulmonary.	Non-pulmonary.	Pulmonary	Non-pulmonary.
1 in 10,000	26	45	0.50	0.40
1 in 5,000	54	70	0.80	1.38
1 in 1,000	65	77	1.30	1.24
1 in 500	72	78	1.58	1.60

* Only about 15 patients in each group were "measured" in all dilutions.

Here again the less severe and non-pulmonary group gives higher percentages, in all tuberculin dilutions, than the more severe phthisical group, the average size of the reaction, however, being about the same in both groups. Both groups included children and adults, but the proportion of children in the non-pulmonary group was greater. The groups were therefore reshuffled according to age.

Comparison of Tuberculous Adults and Children.

Some of the records did not show clearly whether the patients were children or not, so the groups are smaller through the exclusion of uncertain cases—33 adults and 91 children.

TABLE III.—*Tuberculin Reactions in Tuberculous Adults and Children.*

Tuberculin Dilutions.	Percentages Positive		Average Size of Reactions in Centimetres.*	
	Adults.	Children	Adults.	Children.
1 in 10,000	24	40	0.33	0.60
1 in 5,000	54	64	0.80	1.10
1 in 1,000	75	70	1.20	1.50
1 in 500	85	72	1.33	1.83

* Only about 15 patients in each group were "measured" in all dilutions.

The above table suggests that with the higher dilutions tuberculous children react better than tuberculous adults; it will be noticed that the average size of the reaction is slightly greater in children with every strength of tuberculin employed. In this connexion a note by Dr. D. W. Fenwick Jones of the North Wales Sanatorium is of interest. "All babies—surgical—under five," he writes, "reacted well to 1 in 10,000 tuberculin," the reaction appearing late, "only on the sixth day." These infants were further tested with 1 in 5,000, when "they all reacted well on the third day."

This high reactivity of tuberculous infants and children is of importance, especially in view of the fact that non-tuberculous children in the lower age groups differ from healthy adults in giving but a low percentage of "positives." In 28 children "under observation," and without any definite evidence of tuberculous disease, only 7, or 25 per cent., reacted to the intradermal tuberculin test.

Analysis of "Classified" Cases of Pulmonary Tuberculosis.

With the idea, above mentioned, of comparing the tuberculin sensitivity in the more severe and the less severe types, an attempt was made to have the pulmonary cases classified on a system described by me[5] in 1924; but unfortunately only a very small number of cases were so classified amongst the tested patients. The results are given for what they are worth, but it is recognized that the numbers are too small to be satisfactory. All the classified cases were in the third stadium of phthisis, that is to say, suffering from advanced disease. Twenty were of the "recrudescent" or "C" type, twelve of the "initial" or "A" type. The results of the tuberculin tests are given in the following table.

TABLE IV.—*Tuberculin Reactions in "A" Initial and "C" Recrudescent Cases.*

Type of Case.	Total No. of Cases.	Percentages Positive in each Dilution.			
		1 in 10,000.	1 in 5,000.	1 in 1,000.	1 in 500.
"A"	12	16	33	50	50
"C"	20	15	45	65	90

Admitting that the numbers are too small for a conclusive comparison, the tendency seems to be in the direction of more marked reactions in the more favourable "recrudescent" group. The classified cases were separated into fresh groups for consideration from another point of view, according to the classification of Inman, who divided tuberculous cases, in terms of their degree of auto-inoculation as indicated by their temperatures, into "resting febrile," "ambulant febrile," and "ambulant afebrile." Of the 32 patients, 20 were "resting febrile" and 12 "ambulant afebrile." It should be noted that, though the numbers are the same, the cases divided up quite differently from the divisions in Table IV, nearly all the "A" cases being in the "resting febrile" group.

TABLE V.—*Tuberculin Reactions in "Resting Febrile" and "Ambulant Afebrile" Cases.*

Type of Case.	Total No. of Cases.	Percentages Positive in each Dilution.			
		1 in 10,000.	1 in 5,000.	1 in 1,000.	1 in 500.
Resting febrile ...	20	14	38	62	81
Ambulant afebrile	12	16	58	83	100

Again it must be recalled that the numbers are very small; but the figures suggest that the patients sufficiently resistant to hold their temperature in control are also the patients with a sharp power of reaction to tuberculin.

Summary and Conclusions.

It would seem from the above observations that tuberculin sensitivity is at its height in healthy but infected adults, and is still high in those tuberculous persons in whom the disease is taking a relatively benign course, and that it tends to diminish with the gradual deterioration of health consequent on advancing tuberculosis. Whether this fall in sensitivity is the result of the production of anti-bodies capable of neutralizing tuberculo-toxin, or whether it is due to a gradual loss of the power of breaking down tuberculin into its toxic derivatives remains uncertain. The fact that long-continued tuberculin therapy may lead to a toleration of tuberculin, with a corresponding clinical improvement, supports the possibility of a "neutralization" factor, at least in favourable cases, while the fall of tuberculin sensitivity in the advanced stages of non-tuberculous diseases, as well as in the terminal stages of tuberculosis, speaks for a gradual deterioration in the power to deal with tuberculin or to react to it. It may be that the loss of tuberculin sensitivity is due not to one but to several factors, and that different factors may be operative in inhibiting the reaction at different stages of the disease. While it appears certain that a very low percentage of "positive" reactions in any given community goes with a marked racial and individual susceptibility to tuberculosis, it would be a mistake to assume that a high percentage necessarily denotes the possession of a good resistance. The fact that tuberculous children tend to react as well as, or better than, tuberculous adults is against this, since children exhibit a greater liability than adults to generalized tuberculous lesions. It should be recalled, in this connexion, that artificially infected guinea-pigs, though doomed to progressive disease and a fatal termination, almost always show a marked tuberculin sensitivity in the third or fourth week after infection.

A good tuberculin reaction, then, is no guarantee that the patient will be able to control his tuberculosis, nor is a high percentage of reactions, even to so small a quantity of tuberculin as 0.1 c.cm. of a 1 in 10,000 dilution, or 0.01 mg., to be interpreted as meaning that the tested group is necessarily resistant to the evolution of the disease.

With regard to the loss of sensitivity during the progress of a tuberculous infection, the findings of Henry Stuart Willis[6] suggest that, in guinea-pigs chronically infected by inoculation with an attenuated strain, sensitivity is gradually lost, but may be rapidly "whipped up" again by a reinfection. This type of fall in sensitivity probably depends on a "locking up" of the tuberculous foci in the course of spontaneous cure, and is to be distinguished from the "wearing out" of sensitivity in the terminal stages of tuberculosis; the latter being of serious prognostic import.

It is to be noted that no concentrations stronger than 1 in 500 tuberculin were used. The steady rise in the percentages of "positives" with the stronger concentrations justifies the belief that, as found by Happ and Casparis,[3] it should be possible to obtain a positive result in every case, no matter how far advanced, if still stronger tuberculin were given intradermally. In such attempts, however, the possibility of dangerous constitutional reactions should not be lost sight of.

The fact that much larger doses of tuberculin can be tolerated without a general reaction by the intradermal than by the subcutaneous route should recommend the Mendel-Mantoux method to those using tuberculin in treatment.

PHYSIO-THERAPY IN THE TREATMENT OF CHRONIC RHEUMATISM.

BY

FRANK D. HOWITT, M.D., M.R.C.P.,

PHYSICIAN IN CHARGE OF THE PHYSIO-THERAPY AND MASSAGE DEPARTMENTS, PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

THE term "chronic rheumatism," as used somewhat vaguely to cover a number of conditions affecting the joints, muscles, and other skeletal structures, is unfortunate, because it presupposes that these have a pathology identical with that of acute rheumatic fever, a disease which attacks children most frequently, and whose chief ravages fall on the heart. Certain symptoms characteristic of acute rheumatic fever are indeed present in at least one form of chronic rheumatism, but the facts as a whole do not warrant the assumption of a common origin to all forms of rheumatic disease.

The chief lesson to be drawn from modern investigation of rheumatic conditions is the fact that their causes are multiple, just as their manifestations are various, and that each group of cases must be treated according to its individual requirements. The recognition of the important part played by focal sepsis as an etiological factor was a

considerable advance in knowledge, but it is now realized that rheumatism may result from several kinds of toxaemia other than bacterial. There is, for example, the intestinal type, which responds favourably to a lowered calorie intake of food and to high colon lavage; there is the endocrine type, which benefits by administration of thyroid extract; and there is the gouty type, which can be attacked on chemical lines. In many cases clinical differentiation is difficult or impossible; in others more than one etiological factor is operative.

THE ETIOLOGY OF CHRONIC RHEUMATISM.

The theory to be elaborated in this paper is that chronic rheumatism is an allergic state, the antigens producing it being bacterial toxins, the products of bacterial action, or incompletely metabolized protein derivatives with which bacterial action is in no way concerned. Sensitization to any of these antigens may be progressive or capable of periodic recrudescence over long periods of time. The constriction of the smaller blood vessels which results from this sensitized state leads to devitalization, damage, and finally destruction of tissues which even normally have a poor blood supply—for example, fibrous, ligamentous, and articular structures. Such vaso-constriction has been clearly shown to be an integral part of the rheumatic state, and caused probably by the exhaustion of the endocrine-sympathetic system invariably associated with allergy. In some forms of rheumatic disease substances toxic to the above-named tissues may, in addition, accumulate in them and produce inflammatory changes resulting in disease of the proliferative type—for example, rheumatoid arthritis. When destruction results from lack of nutrition the more slowly progressive or atrophic form of the disease results—for example, osteo-arthritis. The various etiological factors must be considered separately.

Infection.

Infection causing arthritis and other forms of rheumatism may be specific—that is, gonococcal, syphilitic, or tuberculous—and careful examination is necessary to exclude these conditions. In their absence it has been customary to call the case one of ordinary rheumatism, by which a subtle imputation is tacitly made against some form of streptococcus. This organism has never been satisfactorily demonstrated in the joints or other structures of rheumatic patients; its presence has been inferred from the frequent discovery of an obvious infective focus, and the occasional amelioration that has followed its eradication. Furthermore, not only is severe rheumatism often found in persons in whom infection is relatively insignificant or apparently absent, but gross sepsis of long standing may be found in patients completely free from rheumatism. Streptococcal infection is responsible, therefore, for only a certain proportion of cases, and, as one would expect, these conform roughly to a certain clinical type—namely, a proliferative polyarthritis of the smaller joints, which frequently runs an acute febrile course, and results in swelling, deformity, and ankylosis.

Intestinal Toxaemia.

This undoubtedly underlies a definite group of chronic rheumatic cases. Patients in this group usually present a toxic appearance; they are unduly pigmented, their musculature is lax and flabby, they are easily fatigued and habitually constipated. It is impossible to be certain whether the antigen concerned is some abnormal intestinal bacterium, or a normal inhabitant of the gut which has acquired pathogenic characteristics, or some product of protein decomposition. But patients in this group, which includes many suffering from recurrent lumbago, sciatica, perineuritis, and fibrositis, respond most favourably to reduction and adjustment of diet and to high colonic lavage.

The Endocrine Factor.

The clinical resemblance between patients suffering from thyroid disorders and those with certain rheumatic diseases leaves no doubt that the relationship between the two conditions is often a close one.[1] Patients with myxoedema frequently suffer from arthritis, and still more frequently are subject to vague aches and pains of a fibrositic nature. Their skin, like that of chronic rheumatic patients, is cold and dry, but subject to periodic attacks of excessive sweating. Chronic rheumatic subjects in this group benefit by taking thyroid extract. On the other hand, many of the more acute cases of systemic rheumatic disease resemble in some respects Graves's disease, in which the skin is hot and flushed, and sweating is profuse. It would seem as though the capillary constriction or dilatation is brought about by some disturbance of the endocrine-sympathetic system, upon which the antigen has a primary effect. Less marked is the effect of hypo-ovarian secretion in rheumatic disorders—a fact not explained by the mere excess of weight these patients sometimes have to carry. The late results of ovariotomy and even hysterectomy are serious, and should always be considered before such operations are undertaken. A similar, though usually temporary, disturbance is often encountered at the menopause.

Osteo-arthritis.

This condition, as a result of the doubt recently thrown upon the theory that it is infective in origin, has come to be regarded as a disease *sui generis*. It attacks, for the most part, the larger joints of older people, and is more common in males than in females. The immediate pathology would appear to be a simple necrosis of the tissues concerned, following prolonged reduction of local blood supply. The disease often remains stationary, and then, after a latent period, progresses. Allied to it, and often occurring coincidently, is true gout. The close relationship of gout with asthma and allied skin affections, and its paroxysmal nature, support the theory that it is anaphylactic in origin, being due to specific hypersensitiveness to certain nucleo-protein containing foodstuffs.

Some Predisposing Factors.

It is now necessary to consider what are the factors which predispose to the production of the allergic state. Among these climate has an important place. Stimulating and invigorating climates tend to produce in the people that live in them the greatest degree of physical and mental fitness.[2] Chronic ill health, particularly rheumatism, may, however, result from attempts to avoid the various discomforts that are necessarily associated with such climates. Sedentary lives, lack of exercise, badly heated and ventilated rooms, and faulty dietetic habits are the harbingers of constipation and of sepsis. Inadequate and deleterious products accumulate in the tissues the skin, wrapped up in clothing, is denied its natural stimulation by sunlight and fresh air, and fulfils only inadequately its various physiological functions.[3] In such circumstances inclement temperature, humidity, and climate become the masters and not the servants of the chronic rheumatic subject. Individual idiosyncrasies in relation to certain localities are also met with, just as in asthma.

All subjects of chronic rheumatism are easily fatigued, and their condition is invariably aggravated by prolonged mental and physical strain. The underlying factor is probably exhaustion of the endocrine-sympathetic system, and here the analogy with thyroid disorders is again apparent. A structure strained by work or exercise will be the first to show this rheumatic tendency—as, for example, in coal-heaver's shoulder or tennis elbow. A fracture which would heal quickly and completely in a normal person will leave pain and stiffness in the rheumatic subject, and the immobilization necessary for its treatment will further aggravate the condition from which he is suffering. Rheumatism is often found in various forms in different members of a family, and a tendency is transmitted from generation to generation.

TREATMENT.

The treatment of rheumatism resolves itself into two problems: (1) the arrest and cure of the disease; (2) the correction of its results.

In streptococcal cases it is important to remove any obvious sepsis without delay, but with care, especially in subacute cases, to avoid a severe reaction, such as might follow, for instance, the wholesale extraction of teeth in

pyorrhoea. Preliminary protein shock treatment is of advantage in such cases. In many patients removal of obvious sepsis is not followed by amelioration of symptoms—a fact which may be explained on the assumption that the organism is still present in various parts of the body in sufficient numbers to produce recurrent resensitization. In the absence of obvious sepsis, the teeth, tonsils, appendix, gall-bladder, and other possible sources of infection should be allowed to remain *in situ*, and attention directed to increasing the patient's general resistance, and to preventing further immobility of the invaded structures. While valuable time is being wasted in a vague search for some hypothetical source of infection, permanent stiffening, adhesions, and other damage may ensue which could have been prevented if treatment had begun earlier.

It is supremely important, particularly in cases of septic origin, accurately to gauge the acuteness or chronicity of the condition—that is to say, the resistance of the patient and his reaction to treatment. For whereas in acute cases treatment involves not only specific measures and good nursing, but absolute rest, it is yet important to commence active treatment as early as possible with the object of preventing further extension of damage in the tissues concerned. It is often most difficult to decide when active treatment may be initiated, but valuable assistance may be obtained from the blood sedimentation test. This test, though in no way specific, depends upon the increased rate of sedimentation of red blood corpuscles which occurs, especially in inflammatory and exudative conditions. If a high reading is recorded the case may be regarded as acute, and palliative measures adopted accordingly. If the reading is within or only slightly above normal limits the case may be regarded as chronic and demanding immediate active treatment. Readings taken at intervals throughout the course of the disease give an accurate index of progress under treatment and of prognosis.

Physio-therapy and Spa Treatment.

Treatment of rheumatism on purely physical lines is administered at various spas under such dignified names as "hydrology" and "balneology." Sometimes a chemical constituent of the water, such as sulphur or potassium, is claimed as a therapeutic omnibus. Sometimes a radio-active substance is found, though its presence may be demonstrable in quantities to appeal only to the homoeopathist. Again, the water may issue from the ground under pressure, and the bubbles from liberated gases claimed to possess peculiar therapeutic properties. Yet these spas undoubtedly do good, and it is important to decide what are the beneficial therapeutic measures common to them all. Briefly they appear to be as follows: (1) the use of heat generally, with the production of a temporary artificial pyrexia, and, locally, combined with massage, movement, and manipulation; (2) stimulation of the skin; and (3) elimination of waste products.

The baths employed in spa treatment for the purpose of applying heat may consist of hot water at varying temperatures, or of hot and cold water alternated; of water vapour of varying density, humidity, and temperature; and of dry hot air. A condition of hyperthermia quickly follows the immersion of the body in a hot bath because loss of heat by evaporation is prevented. In the much hotter dry air of the Turkish bath the body temperature rises hardly at all, because the amount of evaporation is considerable. Vapour baths occupy an intermediate position, and, on the whole, their use has met with the best results in rheumatic cases. Heat produces a general vascular dilatation with transudation of fluid into the tissue spaces. Possibly, also, at normal or subnormal temperature, deleterious substances enter into chemical combination with the tissues and may be dissociated from them only when pyrexia is induced. Such has been shown to occur with lactic acid,[4] and some rheumatic symptoms, particularly pain, may be due to the excess of acids locally. Deviation of the acid base equilibrium in the acid direction is, however, not constant in rheumatic diseases. In acute rheumatic fever, high temperature, accompanied by profuse sweating, may be regarded as a healthy reaction to the disease and Nature's method of eliminating acids and other harmful products. The subject of chronic rheumatism suffers from subnormal temperature and an inactive skin, in which the functions of elimination and oxidation are in abeyance. The beneficial effects of a vapour bath may be due to the fact that it produces both an artificial pyrexia and increased sweating.

Stimulation of the Skin.

It is a common clinical observation that the skin of the rheumatic subject is deranged. It has, for example, a pungent odour, and the sweat glands do not function properly. Lewis,[5] who in his recent observations throws much light on the subject of the reaction of the skin to various stimuli, describes a triple response comprising local dilatation of minute vessels, widespread arteriolar dilatation, and increased permeability, resulting in transudation of fluid into the tissue spaces. He draws attention to the remarkable similarity of the reactions produced when the skin is stimulated and when it is injected with histamine. This similarity he explains by the liberation from the skin of some histamine-like substance, to which he has given the name H-substance. He shows, further, that when the stimulus is applied to the heated skin this substance is liberated diffusely over a wide area, and all the vessels are involved in its removal.

There is no reason to suppose that this H-substance is different from that liberated in conditions of extensive tissue damage and producing "surgical shock." The general extravasation of plasma into extravascular tissue spaces, symptomatic of this condition, tends to wash away injurious substances, and thus acts essentially as a protective mechanism. The skin of the normal subject, especially when he takes sufficient exercise, receives enough daily stimulation to evoke this mechanism. If, then, we assume that the skin of the rheumatic subject is at fault we have a ready explanation of the good results obtained by spa treatment, and of the fact that it matters little what form of skin stimulation is adopted.

The most satisfactory results are obtained when substances producing skin irritation are added to the hot baths in which rheumatic patients are immersed. Sometimes these materials, which include pine, menthol, turpentine, etc., are so irritant that before immersing the patient it is necessary to cover the sensitive parts with vaseline. When the patient is taken from the bath, the temperature and duration of which are regulated according to his condition, he is covered in hot blankets and allowed to sweat profusely for one or two hours. The treatment is strenuous and should only be carried out after a careful clinical examination of the patient.

Elimination of Waste Products.

Every cell in the animal organism requires water, not only to assist in its constant metabolic changes, but to carry away the waste products of metabolism. This action of water is particularly important in rheumatism, but it is astonishing how little water many rheumatic patients drink. In the group attributable to alimentary toxaemia washing out the large bowel by high-colon lavage often effects excellent results. The treatment should be undertaken only by skilled persons, otherwise the tube will tend to curl up in the rectum and no fluid pass into the pelvi-rectal fold. The process should be repeated until clear water is returned, and an even pressure of about two pounds should be maintained; occasionally antiseptics—potassium permanganate, for example—may be added to the water with advantage.

Local Treatment.

Here again heat is the main essential. The objectives, however, are different and a greater heat intensity is usually required. Inhibition of muscular movement in the affected limb tends to retard the normal blood flow essential for the physiological exchange of oxygen and carbon dioxide and the removal of waste products. Heat helps to produce the required hyperaemia. Furthermore, tissues expand under the influence of heat and become more malleable. There are many conditions in which manipu-

fibres are found to be in a state of spasm, movement of any kind being accompanied by pain. Such is the case in true lumbago. If such muscle fibres happen to be traversed by nerves, as, for instance, in the lower cervical region, these nerves become trapped and neuritis results. In such conditions the tissues when heated become more amenable to the influence of massage and movement. The principle underlying the treatment of all chronic rheumatic conditions is the same—namely, to soften the tissues by heat, and, later, to follow this by massage and movement. Force should not be used in the early stages, and then only gradually applied in accordance with the needs of the particular condition. Nerves are sometimes forcibly stretched under an anaesthetic, but even when immediate relief appears to have been achieved, adhesions resulting from such drastic treatment often reproduce the condition even more severely than before.

Methods of Applying Heat.

Heat is commonly applied by conduction. A water fomentation or a dry pad, electrically or otherwise heated, is employed. The temperature at which the sensation of heat gives place to pain is in the neighbourhood of 115° F., and it is therefore not possible to exceed this temperature at the skin surface. If the part is in any way inflamed even this degree of heat cannot be applied. As, however, heat applied by conduction does not penetrate to any appreciable extent, being carried away by the superficial circulation, its use should be confined to the treatment of inflammatory conditions of the skin and immediately subjacent tissues.

Secondly, heat can be applied by radiation. The rays of the violet end of the visible spectrum are converted into heat directly on the skin surface and have very little penetrative power. As the wave-length increases, the rays, before being converted into heat, are able to penetrate to an increasing extent, the luminous and particularly the red waves being employed when a penetrative heating effect is required.[6] In the infra-red region the heat rays again diminish in penetrative power, and are consequently of less value for this purpose. Radiation, though not a good means of applying heat for the end in view, is better than conduction.

Diathermy is used when it is required to concentrate heat in deeply situated tissues. The modern diathermy apparatus produces oscillations of a very high frequency, varying from 800,000 to 1,000,000 per second. The diathermy current has no ionizing effects in the tissues, and as nerve endings cannot appreciate stimuli repeated with a frequency of more than 10,000 per second, it cannot produce sensations, painful or otherwise. A much stronger current can therefore be used than could otherwise be tolerated. This current, passing rapidly to and fro, generates heat in the tissues themselves. The temperature depends on the grouping of these tissues in relation to the path of the current, and on the relative richness or poverty of their blood supply.[7] All of them will, however, be heated to a certain extent. Various precautions have to be taken so as to eliminate the possibility of burns. The pads must be placed at right angles to each other, the parts treated lying directly between them, so that the current may traverse them directly. Such details as the amount of current, the length and frequency of exposures, and the position and type of electrodes can be gauged only as the result of experience.

The value of electrical currents, other than diathermy, in the local treatment of chronic rheumatic diseases is doubtful. It is unlikely that the redistribution of tissue ions caused by the passage of a direct current has any therapeutic effect. Also it is difficult to ascribe any useful purpose to ionic medication; drugs, such as iodine, thus introduced into the system are carried away by the superficial circulation before they can penetrate to the required depth. Beneficial results are sometimes obtained by the use of alternating currents in very chronic cases, and are due probably to their tonic effect upon the wasted muscles, and not to any action upon the disease itself. Sinusoidal baths are perhaps the most useful for this purpose.

SUMMARY.

An attempt has been made to summarize the various aspects of the treatment of "chronic rheumatism." Such treatment must necessarily follow a complete investigation in all cases, and must proceed along systematic lines. Drugs should be used, but not abused, particularly in the relief of pain. Members of the phenazone and exalgin groups, and salicylates, are the most valuable. Iodides probably owe their reputation to their effect in cases associated with endocrine disturbance, but are not so helpful as thyroid extract. Stock vaccines and other protein injections act by producing protein shock and are useful in certain cases. Autogenous vaccines would not appear to have any special advantages. It is suggested that chronic rheumatism is an allergic state produced by a number of widely different antigens in a susceptible subject. For this susceptibility the habits and necessities of modern civilization, especially inadequate stimulation of the skin, are largely to blame. Physio-therapy owes much of its success to the rectification of these errors.

THE DISEASE KNOWN AS MINERS' NYSTAGMUS.*

BY

J. JAMESON EVANS, M.D., F.R.C.S.,

SURGEON TO THE BIRMINGHAM AND MIDLAND EYE HOSPITAL.

For close upon a century coal miners have been known to suffer from ocular trouble associated with their work; in 1831 C. Turner Thackrah wrote in reference to colliers:

> "Their eyes, from swelling of the lids, appear small, and are affected with chronic inflammation and intolerance of full light, and many, after a few years' trial, are obliged . . . to leave the mine."

Nystagmus as a definite disease was first described by Decondé in 1861, but little attention was given to the question until about 1875, when reports, though still somewhat isolated, began to appear in British and Continental medical journals, and were followed by a prolonged and heated discussion as to the causation of the oscillation of the eyeballs. This controversy is still unsettled, and will be carefully avoided in this paper, which proposes to deal with "the disease known as miners' nystagmus whether occurring in miners or others, and whether the symptom of oscillation of the eyeballs be present or not," as notified in the schedule of the Workmen's Compensation Act of 1906 on July 30th, 1913. It may be noted that the earlier observers regarded the disease as a local myopathy of the elevator muscles of the eyes or the result of excessive accommodation, whereas the modern tendency is to refer it to a general fatigue of the whole oculomotor system, or a general neurosis with special manifestations in the oculomotor apparatus.

Since 1907, when miners' nystagmus was added to the schedule of industrial diseases in the Workmen's Compensation Act of 1906, the number of notified cases has steadily risen, and when the definition of the disease was altered in 1913 the Home Office statistics showed a sharp rise in the rate of incidence of nystagmus from 0.16 to 0.26 per cent., and the latter rate has been maintained since. These numbers refer to cases of invalidity from the disease, and must not be confused with the rate of prevalence of nystagmus in miners. Oscillation of the eyeballs, it has been estimated, may be found in about 25 per cent.

* Read at a meeting of the Midland Ophthalmological Society, December, 1928.

of working miners, but something like 99 per cent. of them are unaware of the condition. It is obvious, therefore, that oscillation of the eyeballs *per se* need not be a cause of invalidity, and when a miner who has shown oscillations becomes incapacitated for work some new factor is introduced, and this in itself, or in addition to the oscillations, gives rise to working incapacity. There is no doubt that severe oscillations in the primary positions of the eyes, when mere standing up causes giddiness and marked unsteadiness or reeling, would be regarded as a cause for total disability. In many cases, however, when oscillations are difficult or impossible to elicit, subjective symptoms are apparently more distressing than in the cases with severe oscillations.

It would appear that there is no strict relationship between the degree of oscillation and the severity of such subjective symptoms as giddiness, headaches, sleeplessness, photophobia, night-blindness, and mental depression. In fact, these symptoms often appear to increase as the oscillations diminish. During the last few years these "nervous" symptoms have increased enormously in frequency, perhaps in intensity, and at the present time they may be said to dominate the whole picture of miners' nystagmus. From notes of cases of miners' nystagmus referred to me for compensation purposes, I find that during the years 1910–19 about 5 per cent. only presented anxiety neurotic symptoms of any degree, whereas among those examined during the period 1919–24 29 per cent. presented very definite symptoms of the kind. The figures with regard to giddiness and headache are still more striking.

Giddiness complained of:

1910–19	... ...	50 per cent. of cases examined.
1919–24	... ...	78 per cent. ,, ,,

Headache complained of:

1910–19	... ...	30 per cent. of cases examined.
1919–24	... ...	70 per cent. ,, ,,

What is the explanation of this change, which amounts to a definite alteration in type, if not to a new disease? I think there can be little doubt but that the widening of the definition of miners' nystagmus in 1913 is responsible for this change in type, as well as for the extraordinary increase in the number of cases certified. This development is in no sense to be regarded as due to increase of malingering; in fact, deliberate malingering appears, from the same records referred to above, to be less frequent. From 1910 to 1919 it was about 8 per cent.; from 1919 to 1923, about 4 per cent. The development must be regarded as the inevitable result of making it an easy matter (by the Act) for the neurotic to escape from a psychologically intolerable position caused by failure to adapt himself to his environment.

The nervous symptoms referred to are headache, giddiness, photophobia, night-blindness, or rather a fear of going about in the dusk or midlights, sleeplessness, with distressing dreams during the short periods of sleep, amblyopia, perhaps contraction of visual fields, mental depression, and often a change of character, sometimes passing to definite mental illness and even suicidal tendencies. When these symptoms are met with we find tremors of the head and limbs, lid spasm, and endocrino-sympathetic disturbances, such as disordered action of the heart, vaso-secretory disturbances, etc. These symptoms differ in no way from the symptoms of psychoneurosis met with in other spheres and among other members of the community, and it is obvious that a miner might be incapacitated by such a neurosis without showing any oscillations of the eyeballs at all. Hence the justification for the alteration in the terms of the Act in 1913. It is a fair question to ask, What is the relation of the nystagmus to the psychoneurotic symptoms? I am inclined to think that it acts as one of the exciting factors, but an important one. The coal miner, in this country at any rate, seems to be peculiarly predisposed to the development of a psychoneurosis owing to the nature of his work, his environment, and heredity (through inbreeding). A state of oscillation of the eyeballs would probably excite in him the psychopathological feature of fear already present to some extent in consequence of the recognized riskiness of coal mining, and possibly also of its association with scotopic vision—we are all a bit "afraid of going home in the dark." This would be followed by anxiety as to the effects of the oscillation on his sight, and on his general health and his capacity for earning a living and keeping the home together. His condition would be aggravated by the knowledge that many of his fellow workers have been incapacitated from work for prolonged periods through nystagmus. Any inadvertent remark by doctor, solicitor, or friend as to possible loss of sight will inevitably confirm him in his neurotic state. Some slight irritation of the lids, due perhaps to conjunctivitis, to which miners are particularly liable, sets up headache and spasm of the lid and other muscles of the face. These, along with his fear and anxiety, produce loss of sleep, which in itself is an aggravating factor in the complex, and as a means of easy escape from a distressing psychological position he resorts to the avenue of the Workmen's Compensation Act.

If we assume that these symptoms are due to causes which have, perhaps justifiably, been described as the "dungeon complex," are we to regard them as a cause of disability, and if so, whether for pit work or for surface work or for all work? In many cases the giddiness set up by mere stooping—such as in tying a bootlace—or sudden movement is so intense that the patient is unable to stand, and in such cases it is obvious the man is incapable of doing any work, except perhaps in the sitting position. Percival is convinced that the incapacity for working in the pit varies directly as the degree of giddiness on stooping, by which he means "that if a patient shows nystagmus in a dark room, and the other signs such as the characteristic tremors, rapidity of pulse, etc., giddiness sufficient to render him incapable of pit work may be reasonably attributed to miners' nystagmus." But this is taking rather a restricted view of the causes of disability in miners' nystagmus, and it does not enlighten us as to what degree of giddiness is sufficient to render a man incapable of pit work. It must be that a good many miners suffering from giddiness of varying degrees and causation are capable of earning full wages at the coal face, while some who do not complain particularly of giddiness appear to suffer so acutely from pains in the head when they are asked to fix a point of light that it seems hopeless to expect them to do any form of work.

The question has been raised as to whether a miner who has once suffered from incapacitating nystagmus should be allowed to work in the mine again; the argument being that under the conditions of coal mining the disease is bound to recur, even if it is admitted that it may be cured for a time. I am not convinced that we possess any statistics or other form of information which would enable us to give an incontrovertible opinion in the matter. The vast majority of nystagmus patients do return to their old work and continue to earn full wages. An analysis of cases I have reported upon gives the following results. Returns cases (two or three attacks): 1910–19, 9.5 per cent.; 1919–24, 14.2 per cent. The percentages of third attacks were 1.5 and 4.7 for the same periods. There was no indication that the severity or the duration of recurrent attacks was any greater than that of the initial attack; neither did the working periods appear to get increasingly shorter. It must be remembered that relapses, like the original attack, are generally due to factors outside the actual occupation—for example, physical illness or injury, domestic worries, and particularly the economic state of the coal industry and of the labour market generally. Thus there was a tremendous accession of nystagmus cases, primary and otherwise, during the period of the coal stoppage, and there is always the same rush to the certifying surgeon when a mine closes down. It does not appear, therefore, that it is essential for the nystagmic miner to change his occupation in all cases. It is not an easy matter for anyone to change his occupation in middle or later life, and it is particularly difficult in the case of a miner, who has probably never had experience of any occupation other than his own specialized work. I do not think the miner himself is particularly enamoured of the suggested change, and the present state of the labour market does not

encourage it. For the same reasons industrial colonies staffed by disabled miners cannot be regarded as a sound economic proposition.

My main purpose in bringing up the question of miners' nystagmus again is not to discuss its etiology and symptomatology, but to appeal to ophthalmologists to take interest in the matter of its curative treatment. On the preventive side it must be admitted that a vast amount of work has been done and much money spent, though the tangible results so far have not been very great. Improvement in the hygiene and illumination of the mines seems to have had some salutary effect. Probably still better illumination, which would definitely substitute photopic for scotopic vision, would result in a very definite reduction in the incidence of miners' nystagmus. But what are we doing to relieve the patient who is already afflicted with this truly distressing complaint? There are hundreds of cases not receiving any form of treatment, apart from encouragement to get some work to do to avoid the evils of idleness and introspection. I consider this a reflection on the enterprise and public spirit of the ophthalmologists in mining areas. It may be true "that there would appear to be a disease, miners' nystagmus, the nature of which, as far as the eyes are concerned, we, as ophthalmic surgeons, can appreciate, accurately measure, and record; there is another disease, miners' psychoneurosis, of which we, as ophthalmic surgeons, have no special knowledge,"[1] but that is no reason why we should not make good that knowledge, with or without the help of psychological and other experts. The psychologists could deal with the factors of innate nervous instability and the psychic disability, but we could certainly deal with the toxic factor, which is probably present in all cases. The mining engineer will attend to the question of toxicity due to exogenous agents such as gases, but it should be our duty to find out the part played by endogenous toxins in establishing and sustaining the disease, and to adopt methods to counteract their action.

Mr. Frank Thomas of Swansea has obtained some favourable results by dealing with obvious oral and nasal sepsis in these cases, but if we are to attack the problem properly we shall need to go into the whole question of sepsis, and especially of intestinal toxaemia, and its correction. Investigations into these matters involve the institutional treatment of the patients, and obviously the institution must have the staff and equipment necessary to carry out these investigations.

A NEW METHOD OF APPROACH IN GASTRIC SURGERY.

BY

DIGBY CHAMBERLAIN, CH.M., F.R.C.S.,

HONORARY ASSISTANT SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE two cases of carcinoma of the stomach which I am about to describe in detail belong to a small group which at first sight might appear to be inoperable. From the point of view of a radical excision of carcinoma of the stomach cases fall into three categories. There are (1) cases in which the growth is confined to the stomach, where the stomach is not fixed, and which are suitable for an immediate partial gastrectomy; (2) cases where there are secondary deposits in the liver or elsewhere, which are obviously inoperable; and (3) cases where there are no secondary deposits, but where on account of the local conditions, the size and fixation of the growth, it is doubtful whether an excision can be done. It is to this last group that these two cases belong. They were both operated on by Sir Berkeley Moynihan, under whose care they were at the General Infirmary, Leeds.

Briefly, the method is to open the abdomen and give a big dose of deep x rays directly on to the tumour. A second operation is done six weeks later, when the growth is found to be considerably shrunken in size, and to be much more freely movable.

CASE I.

A woman, aged 45 years, was admitted with a three years' history of attacks of abdominal pain and nausea. Five months previously she had begun to vomit, and since that time she had been unable to retain any solid food whatever. For the last two months she had been in bed. There was a fixed tumour palpable in the epigastrium. An x-ray examination showed a filling defect in the stomach, involving both curvatures and extending from the pylorus about two-thirds of the way to the oesophageal opening. A fractional test meal showed a complete absence of free hydrochloric acid. She was given two transfusions of blood, and on August 31st, 1925, the abdomen was opened, using hedonal as an anaesthetic. A large mass of growth was found in the stomach; its extent was as shown by the x-ray examination, and the condition was described as a leather-bottle stomach. Glands were present along both curvatures, but there was no sign of any malignant deposit elsewhere. The abdominal wall was retracted, everything except the growth protected by mackintosh clothes and lead plates, and the growth itself was exposed to the direct action of the deep x rays for forty minutes. The abdomen was then closed and the patient sent to a convalescent home.

A second operation was done on October 12th, when the growth was found to have shrunk to roughly half its original size. In addition, it could be moved about quite freely and a partial gastrectomy was done without much difficulty. The patient had an uninterrupted convalescence and left hospital finally on November 3rd. She was still in good health four and a half years after the operation, except for a secondary anaemia. A recent blood count was as follows: Erythrocytes 4,180,000 per c.mm., haemoglobin 36 per cent., colour index 0.42, leucocytes 6,100 per c.mm.—a reading which is very definitely not of the pernicious type.

CASE II.

A man, aged 60, was admitted in July, 1924, with a history of indigestion since the preceding December. He complained of pain coming on three to four hours after a meal, and said that food relieved his pain. His appetite was fair, he had not lost much weight, but looked pale. An x-ray examination showed a filling defect in the middle third of the stomach, and a test meal revealed an absence of free hydrochloric acid. He was given three transfusions of blood, and on August 8th his abdomen was opened under local anaesthesia. There was a growth in the middle third of the stomach, mostly on the anterior surface. It extended into the great omentum and appeared to be dangerously close to the transverse colon. It was adherent posteriorly, so that it was quite impossible to lift the stomach up into the wound. There were no secondary deposits elsewhere. As in the previous case, an application of deep x rays was given directly to the growth for thirty minutes.

The second operation was done on October 1st, when it was found that the growth had shrunk considerably in size, that the posterior fixation had disappeared, and that it was quite possible to get between it and the transverse colon. The stomach was removed, and a note made at the time says that the upper division of the stomach was very close to the edge of the growth. The patient left hospital on November 11th and is still in good health more than three years after the operation.

A pathological examination of the specimen showed it to have been a spheroidal-celled adeno-carcinoma. The interesting point about this case is that in spite of the stomach having been divided closer to the growth than would ordinarily have been considered advisable there has been no recurrence. This is what we might expect, for as well as an action on the main mass of the growth, an effect must be produced on the clinically imperceptible permeation round it.

These two cases illustrate very well the changing of an apparently inoperable into a definitely operable state. At first sight there is no doubt that it would have been absolutely impossible to attempt to excise the stomach, while at the second operation the conditions for its removal could hardly have been more favourable.

An alternative method is, of course, to give a preliminary exposure of deep x rays to every case of carcinoma of the stomach which is to be operated on. To give a dose of the strength which can be applied directly to the growth would be to run the risk of an x-ray burn, and experience shows that one big dose is considerably more efficacious than a number of smaller applications applied to the growth at intervals by the cross-fire method.

Cases of this type belong to a very small group, for the conditions must be as I have described them for this line of treatment to be possible. It is a very high recommendation for the method that these two patients, the only ones to undergo treatment by this method, are alive without any signs of recurrence, in the one case four and a half years, and in the other five and a half years after operation.

ACUTE HAEMORRHAGIC PANCREATITIS WITH TUBERCULOUS DISEASE OF PANCREAS.

BY

J. A. MUNRO CAMERON, M.B.,

ASSISTANT PATHOLOGIST, VICTORIA INFIRMARY, GLASGOW;

AND

MARJORIE GILLESPIE, M.B.,

MUIRHEAD RESEARCH SCHOLAR IN PATHOLOGY, VICTORIA INFIRMARY, GLASGOW.

TUBERCULOSIS of the pancreas, appearing either in the miliary form or as a tuberculoma, is an uncommon *post-mortem* finding, and in cases such as the following, where a tuberculous process produced an acute haemorrhagic pancreatitis, a very unusual condition is encountered.

Clinical History.—A male patient, aged 66, was admitted to Dr. Douglas Russell's wards at the Victoria Infirmary, Glasgow, on July 22nd, 1928, deeply cyanosed and collapsed. Until the age of 42 he was stated to have been a normally healthy man, but at that time he had an illness, the nature of which we could not discover, which subsequently left him in indifferent health. Two and a half years ago he had broncho-pneumonia, became still more debilitated, and for five days before admission he had been unable to move through weakness and breathlessness. During the month prior to this he complained of flatulent distension and "stomach" pain, and his colour showed progressive cyanosis.

Condition on Admission.—On admission he was pale and cyanosed, the bluish coloration, of rather a striking character, extending over the whole body. His breathing was very laboured and rapid, and suggested pneumonia; the temperature was 99.4° F., respirations 32. The right side moved more freely; on percussion the left side was hyper-resonant over the front, and respiratory murmur was very harsh, with prolongation of the expiratory phase. The abdomen was distended, but not tense, and there appeared to be no tenderness.

No improvement in the patient's condition occurred, and he died two days after admission.

Post-mortem Examination.

The heart was of normal size, with pale muscle and atheromatous coronary vessels. The valves were healthy and competent.

The left lung was firmly adherent at the apex, and was studded with tuberculous nodules. Surrounded by fibrosed lung tissue and at the apex there was a small cavity of about the size of a walnut. The right lung was free, but similarly invaded, and there was some pneumonic consolidation at the base. The pleurae and pericardium contained some excess of fluid.

The liver, which was adherent to the diaphragm, was bluish-black on the surface, and on section was firm, and suggested cirrhosis. A cholesterin stone was found in the gall-bladder; no calculi were seen in the common bile duct or at the ampulla of Vater.

The spleen was much enlarged, and showed a similar dark pigmentation.

The pancreas was generally congested and firm; the head was much increased in size, rather difficult to remove from its blood-stained surroundings, and a section showed a large area of haemorrhage, approximately 2 inches by 1/2 inch, extending into the body of the organ and with smaller areas of necrosis surrounding it.

The suprarenals were enlarged, the medulla being rather soft and showing some cavitation.

The peritoneum contained some blood-stained fluid, and the omentum was soft and felt greasy, and some definite areas of fat necrosis were noted.

The examination of the other organs revealed nothing of any importance.

Microscopic Examination.—The lungs showed areas of catarrhal pneumonia, caseation, and occasional tuberculous giant cells. The spleen showed some caseous foci with definite tubercles and an extreme degree of congestion. The liver showed generally a fine cirrhosis, with some definite tubercles. Tuberculous invasion of the medulla was noted in the left suprarenal, and lymphocytic areas were common. The pancreas, sectioned at various levels, showed areas of necrosis surrounded by inflammatory cells, and in places extensive haemorrhages. Giant cells were occasionally found on the edge of a caseous area, and the vessels of the organ were generally thickened; sometimes this appeared to be confined to the intima, at others the entire vessel wall was affected.

COMMENT.

The pathology of acute haemorrhagic pancreatitis is not yet satisfactorily explained. The frequency of its association with gall-stones and with stones lodged near the ampulla of Vater suggests that the immediate causation is the entrance of bile into the pancreatic duct. Experimentally this has been proved to cause necrosis of the pancreatic tissue, and the injection of a variety of chemical irritants—zinc chloride, papain, artificial gastric juice—has been followed by lesions very similar to those present in subjects dying of haemorrhagic pancreatitis. In this particular case a gall-stone was present in the gall-bladder, and no other stone was found in the pancreas or the ducts; certainly a minute stone may have been missed, but the definite tuberculous lesion of the pancreas, the thickening of many of the vessels, suggests rather that the cause of the haemorrhage and necrosis could not be referred to the entrance of bile into the duct of Wirsung, but rather to erosion of a vessel or vessels by the tuberculous process.

The early occurrence of death in this disease is likewise not very clear. Some authorities believe that this is due to pressure on the solar plexus, and inflammatory changes in the sympathetic ganglia have been described. Others refer the rapidity of the fatal symptoms to absorption of protein derivatives due to the action of pancreatic juices on its own necrosed tissue. The latter view has some experimental support, and the characteristic cyanosis tends to confirm a biochemical change of some nature. It is more than probable that both factors are of importance.

Our thanks are due to Dr. Douglas Russell for his clinical notes.

CARDIAC DISEASE AMONG SOUTH AFRICAN NON-EUROPEANS.

(PRELIMINARY NOTE.)

BY

H. L. HEIMANN, M.D., M.R.C.P.,

EXTRA HONORARY PHYSICIAN, JOHANNESBURG GENERAL HOSPITAL; CLINICAL LECTURER, UNIVERSITY OF THE WITWATERSRAND;

WITH THE HELP OF

A. S. STRACHAN, M.B., B.CH.,

PATHOLOGIST TO THE SOUTH AFRICAN INSTITUTE OF MEDICAL RESEARCH AND SENIOR LECTURER IN PATHOLOGY, UNIVERSITY OF WITWATERSRAND,

AND

S. C. HEYMAN, B.Sc., M.B., B.CH.,

LATE HOUSE-PHYSICIAN, NON-EUROPEAN HOSPITAL, JOHANNESBURG.

THIS investigation was suggested by the following quotation from *Rheumatic Heart Disease* by Dr. Carey Coombs: "The disease (pancarditis) due to rheumatism is rare among natives of China and India. I have never heard of the disease among the natives of Africa."

I have analysed the notes of the non-European patients of the Johannesburg General Hospital with the able help of my house-physician, Dr. S. C. Heyman, and with the kind permission of my colleagues on the staff. Dr. Strachan of the South African Institute of Medical Research has acted with me, and has checked from *post-mortem* records the accounts of the patients who died. Although the cases are few in number, they serve as a useful guide for future investigation. From these records we have excluded all patients of Asiatic origin as they have no place in the subject under consideration. About one-fifth of the total cases are of mixed stock (Eurafrican). In the Kaffirs, it must be remembered, we are dealing with a people in whom the way of life differs from that of Europeans. The Kaffir, however, has been in direct contact with European civilization for a number of years, and his mode of life has accordingly changed. What effect the change has had in the incidence of cardiac disease among this people it is impossible to say.

In this article we are writing in the main of the native who works in towns. As a rule the latter portion of his life is spent in his kraal, and there he dies, so that we are dealing principally with the Kaffir between the ages of 16 and 50. Such an individual spends half his life working in the towns and half at his kraal or home, where he tills the soil, shepherds his flock, or builds his dwelling. In the town his occupation is domestic, shop, or mine labour; it is never sedentary. In this short survey we have had to neglect the occupational factor, since mine labourers in active occupation are restricted to the mine hospitals and do not come into our hospital; and, for the reason mentioned already, Kaffirs are not often admitted for diseases of old age. On the other hand, our sick are drawn from a wide area, though the majority are of local origin at the time of invalidism.

Our analysis dates from March, 1924, to March, 1928. The cases included are all those of which we were reasonably sure of the diagnosis. Note-taking is difficult in the

native. Histories are generally short, indecisive, and variable from day to day, even with interpretation from the native tongue. In all we took the notes of 153 cases, of which 120 were Kaffirs, 31 were Eurafricans, and 2 were Hottentots. A striking fact is the huge mortality—81, or more than 50 per cent., died in hospital. This is attributable to the extremely late stage of disease in which they were admitted. Application for admission by a native is tardy, for he is afraid of hospital, and he is poor and works to the end.

A general survey of all cases will be taken first, and the etiology and characteristics will be considered; then a few particular aspects will be dealt with.

Etiology of Cardiac Disease in the Native.

One knows that syphilis is rife among the coloured races of South Africa, and one has a rough appreciation that its incidence is variable in different localities and with different tribes. It was with no little surprise, therefore, that we found that the commonest group of heart lesions were those of the rheumatic type. Of this etiology there were in all 64 cases, of which 42 were Kaffirs, 16 Cape people, and one Hottentot. Approximately two-fifths of all the cases in this series were of rheumatic type. Of the 64 cases only about one-sixth gave a rheumatic history, but this is in accordance with what I have already said about note-taking in the native.

The etiology of the others was judged from the clinical findings and from *post-mortem* records. On the clinical findings alone we are open to some criticism, but these findings conformed to those accepted in Europeans and to the necropsies of 16 cases. The sex incidence in these cases was almost equal, and the ages of the patients lay between 8 and 47. There were 18 deaths, 12 among the Kaffirs and 6 among the Eurafricans. The average age at death was round about 30.

Of syphilitic conditions there were 39 cases, of which 31 were Kaffirs, 7 were Eurafricans, and one was a Hottentot. There were 24 males and 15 females, and 16 deaths, 13 among the Kaffirs and 3 among the Cape people. The etiology of many of these conditions was confirmed by *post-mortem* findings; in the other cases the Wassermann reaction was positive and the clinical condition corresponded to the description of syphilitic cardiovascular states in Europeans.

There were 25 patients with degenerative lesions; 18 were Kaffirs, 6 were Cape people, and one was a Hottentot. There were 23 deaths—17 Kaffirs and 6 Cape people—of these the majority came to necropsy and the etiology was confirmed.

There were 14 cases of bacterial endocarditis—12 Kaffirs and 2 Eurafricans; 9 were males and 5 females. All the cases were fatal.

Of pericarditic lesions there were 8; 6 were definitely non-rheumatic and 2 were of doubtful origin. All these patients were Kaffir males, and all died.

Of unclassified patients there were 3, all Kaffir males. One was a man whose heart was the seat of an interstitial myocarditis due to cysticercus—a lesion confined to the heart muscle; the second was a case of aortic regurgitation of doubtful origin, and the third a myocarditis of doubtful etiology.

Rheumatic Conditions of the Valves.

The lesions were of the same type as occurs in the European. In 41 cases the mitral valve alone was involved, there being either stenosis or regurgitation or both; in 10 cases there was aortic regurgitation alone, and in 13 cases both aortic and mitral valves were involved. A very small percentage of these cases gave a rheumatic history. Six had auricular fibrillation, of which 5 were associated with mitral disease, one with aortic disease. The clinical manifestations of failure of compensation were similar to those in white people, and reacted to digitalis and other drugs in a similar manner. Rheumatic nodules are found occasionally, but were not mentioned in the records of this series of cases. In one only of these cases was an attack of tonsillitis noted, and the incidence of tonsillar infections in this type of cardiac case seems to be rare, but this is a point which needs further elucidation. In none of these cases was pulmonary tuberculosis a concomitant disease, although this condition is rife among the native population. The *post-mortem* changes in the heart and other viscera were similar to those found in Europeans. The ages of the patients with auricular fibrillation varied from 18 to 50. None of these cases died in hospital, a fact I attribute to the crippling decompensation from which these patients suffer and their quick reaction to the digitalis group of drugs. I suspect that these patients proceeded to their kraals and died for want of appropriate treatment. Pericarditis occurred in two cases, both fatal and confirmed at necropsy. Acute nephritis occurred in one case and infarction of the lung in one case.

Syphilitic Disease.

The average age of these patients was 47, and ranged from 26 to 70. This agrees with the age in Europeans. It is a curious fact, however, that tabes dorsalis, which occurs most commonly in the Europeans in the fifth decade, is a rare condition among the natives, though occasional cases do occur; primary optic atrophy due to syphilis is far commoner. I mention this as I have pointed out elsewhere that cardio-vascular syphilis and early signs of locomotor ataxia occur together in a certain percentage of white cases. Of the total of 33 cases 10 (8 Kaffir, 1 coloured, 1 Hottentot) exhibited aneurysm of the aortic arch (2 abdominal, 1 descending thoracic aorta, and the remainder aortic arch or descending thoracic aorta), and 4 of these were in women; 10 out of 33 is a far bigger proportion of aneurysmal occurrence than happens in European syphilis, and is probably accounted for by lack of early treatment in these cases. It is also noteworthy that 14 of the total number of cases occurred in women, whereas in Europeans the incidence is only one in ten. I ascribe the increased incidence to the common occurrence of promiscuous intercourse between town-living natives, and also to the ignorance of the native as to the nature of syphilis, so that he does not come for treatment in the primary stages.

The commonest pathological condition was that of aortic regurgitation, which occurred in more than half the cases. Auricular fibrillation was present in one case, and I have seen one case of auricular flutter, which is not included in this series. Syphilitic cardio-vascular degeneration apart from aortic regurgitation was also common, and there was one case of syphilitic cerebral thrombosis. In many of the cases there was enlargement of the heart to the left, in some of which there was no aortic regurgitation (thus conforming to cases described in the European). When failure of compensation occurred the symptoms and signs were similar to those in the European. It is my impression that both auricular fibrillation and angina pectoris are rarer in syphilitic cardio-vascular disease in the native than they are in the white. Enlarged epitrochlear glands are common in these cases, and occasionally one finds tertiary syphilis of the bones or a fibrotic change in the lung, probably of syphilitic nature.

Degenerative Lesions of the Heart and Blood Vessels.

The large death rate in these lesions has already been quoted. The ages ranged from 27 (a case of interstitial nephritis) to 68, the average being 48. Five of these cases were accompanied by nephritis, of which one patient had a subacute exacerbation at the time of death. In one case the blood pressure was 268/165, but unfortunately in many cases the blood pressure was not recorded. In two cases there was enlargement of the right side of the heart only, and in both these cases there was myocardial degeneration—in one accompanied by cirrhosis of the liver. (In the Kaffir the etiology of this type of primary cardiac degeneration without enlargement to the left is obscure; there is no thickening of the blood vessels, nor is there much raising of the blood pressure; it is not a senile change, since one of the two cases was aged 37 years.) In the majority of cases the heart was greatly enlarged. Aortic regurgitation occurred in 3 cases (one with aortic stenosis), one was complicated by hydatid disease of the brain. The majority of the cases died of heart failure. Other causes of death were kidney insufficiency, cerebral thrombosis with lobar pneumonia, peritonitis, and pericarditis. Relative

mitral incompetency occurred, as might be expected. I have not yet seen a case of pure hyperpiesis in the native without arterial thickening, but I have seen two patients, not included in this series, where the systolic blood pressure was over 300 mm. of mercury. They first came to the ophthalmic surgeon (the late Dr. M. Baranov) for failure of vision, which was due to retinitis.

The actual causes of arterial thickening in the native are as obscure as in the white. Most of them do heavy work, some of them are alcoholics, few of them are subjected to great mental stress.

Acute and Subacute Bacterial Endocarditis.

The bacteriology of these cases has not been elicited in this series. In one case the streptococcus and *Bacillus coli* were cultured and in another a pure streptococcus. In two of the fourteen cases the Wassermann reaction was positive, and in one there was an underlying chronic endocarditis of the mitral valve alone. The clinical findings were similar to those in Europeans, and these were confirmed by necropsies. Heart failure, cerebral embolism, or infarctions were responsible for the deaths.

There is great difficulty in the diagnosis of these cases. Acute tuberculosis and typhoid fever are both rife, and with the scanty history the diagnosis is often impossible in early stages. Given the complication of malaria with one of these acute illnesses, the differential diagnosis is still more difficult. In all the cases the heart was enlarged, and in all the disease was fatal within a comparatively short space of time. None of them showed any remissions —that is, they were all of the acute form of the disease.

Unclassified Cases.

Of three unclassified cases one suffered from aortic regurgitation, one from a myocarditis of unknown etiology, and the third from an infection of the myocardium by the cysticercus. A generalized infection with cysticercus is not uncommon among the natives.

Some Uncommon Types of Cardiac Disease.

Auricular flutter due to syphilitic myocarditis is rare, but has been described. One such case occurred in a native female under my care; this has not been included in the series. In this case normal rhythm was induced by digitalis-quinidine therapy, antisyphilitic measures also being carried out.

Syphilitic Pericarditis.—This is seen among natives, but is rare. It appears as an effusion accompanied by failure of compensation; the clinical signs are those of a pericardial effusion. Paracentesis of the fluid shows it to be blood-stained, as I have been told, and this, with vigorous syphilitic measures, is sometimes successful in treatment.

Tuberculous Pericarditis.—The pericardial lesion presents itself with the physical signs of a large effusion with extreme failure of compensation, accompanied occasionally by oedema of the arms as well. Paracentesis gives no fluid. Necropsy reveals that visceral and parietal pericardial sites are occupied by solid plaques of tuberculous material, sometimes half an inch thick. The myocardium is sometimes much weakened by infiltration with tuberculous material. The whole organ appears to be enlarged.

Conclusion.

It does not appear that there is a wide divergence between the etiology, pathology, and clinical signs of heart disease in Europeans and African non-Europeans. In this paper stress has been laid on etiological factors. It has been pointed out that the mortality rate is high in the series; this must mean that the course of cardiac disease is shorter in the non-European, or that the patient is admitted in a later stage of the disease than the European; or both factors may come into play.

Some important etiological factor in the causation of rheumatic fever might be elucidated by comparing the Kaffirs living altogether in the native state with the Kaffirs in the towns. The medical history of the Kaffir before the influence of European civilization affected him is unfortunately not to be ascertained. The climate of South Africa, speaking generally, is one of sunshine, and is hot and dry. It seems that climatic conditions as an etiological factor in the causation of rheumatism must be discountenanced here.

Nasopharyngeal infections or bad teeth cannot be dismissed as factors as they commonly occur in hospital patients. Their evidence in this series has not been determined. The dietary factor is a very variable one in the series; it is difficult to obtain exact knowledge, but the Kaffir, as a rule, takes a diet of greater carbohydrate content and less fat and vitamin constituent than the European.

As regards non-rheumatic cases, little can be added to the facts already quoted. It must be reaffirmed that the mortality among the patients with degenerative types of lesion is extremely high, and that the syphilities have a high aneurysm incidence.

Much work is yet to be done, especially in diseases of rheumatic etiology. It is to be hoped that one day a commission will be instituted to inquire into this—directly to help the native, indirectly to elucidate factors in the causation of acute rheumatism—and so throw light on a very baffling medical question.

A CASE OF GRADENIGO'S SYNDROME.

BY

D. B. SUTTON, M.B., B.S., M.R.C.S., D.L.O.,

ASSISTANT SURGEON IN CHARGE OF EAR, NOSE, AND THROAT DEPARTMENT, GREAT YARMOUTH HOSPITAL.

THE association of temporo-parietal pain and paralysis of the sixth cranial nerve in connexion with an acute otitis media on the same side was pointed out by Gradenigo in 1904. The attack of otitis media may be of short duration, and the abducent paralysis may follow in a few days or in one or more months.

Considerable attention has lately been paid to this syndrome, but yet it seems sufficiently rare to make the following case worthy of report. Symonds[1] quotes Sears as having recently collected records of 317 cases since Gradenigo's paper in 1904, but he states that in some of these cases the sixth nerve palsy appeared to be secondary to extradural or cerebral abscess, and therefore should not properly be included in the category of Gradenigo's syndrome. In the case recorded below an interesting feature is the fifth nerve distribution of the pain in addition to the usual temporo-parietal situation.

A married woman, aged 44, was admitted to this hospital under Dr. V. H. Blake on December 17th, 1927, for severe neuralgia of the left side of the head in association with acute otitis media on that side. She had been under Dr. Blake's care since December 4th, when she complained of pain in both ears. The next day her temperature rose to 100° F., and both tympanic membranes were inflamed. Her temperature continued between 99° and 100° F. till December 9th, when it became normal. On December 10th inflammation in the right ear was settling down, but the left tympanic membrane had perforated. Discharge continued for only four days, and when admitted on December 17th her temperature was normal, but the left drum was again bulging. Whilst in hospital her temperature remained normal till December 26th, but the neuralgia was persistent. It was temporo-parietal and facial in distribution at first, but later only temporo-parietal. The pain was so severe that narcotics had to be administered every evening, and even then she passed only indifferent nights.

Diplopia was first noticed on December 23rd, and on the following day Dr. Blake asked me to see the case and carry out any appropriate treatment. The temperature and pulse were then normal. The patient's appearance was that of weariness from continuous pain. There was no oedema or tenderness over the left mastoid, but there was slight meatal tenderness. Rinne's test was negative on both sides, and Weber's test was referred to the left ear. Bone conduction was slightly diminished. The stop-watch could be heard at a distance of 1 inch with the right ear, but not at all with the left. The whispered voice could be heard at rather more than 4 feet on the right side, but on the left it was only audible at 6 inches. The left tympanic membrane was dull and opaque, and there was a marked bulge of Shrapnell's membrane of a dull red colour. On the right side the membrane was retracted. There was complete paralysis of the sixth left cranial nerve. Other movements of that eye and all movements of the other eye were good. The pupils reacted normally to accommodation and light, and there was no nystagmus. There was some hyperaesthesia of the left side of the face as tested with

cotton-wool and a pin, but it was not marked. There was no facial weakness, and no paresis of the ninth, tenth, eleventh, or twelfth left cranial nerve. There was no retropharyngeal swelling. Cerebration was apparently normal. There was no stiffness of cervical muscles, and abdominal reflexes, knee-jerks, plantar reflexes, etc., were all normal. The fundi were examined by Mr. William Wyllys and reported normal.

The further progress of the case was as follows:

December 25th: There was pain during the night, but the patient is easier this morning.

December 26th: Pain was very severe during the latter part of yesterday and all the night in spite of the narcotics. She is now in great pain. Begs for something to be done. Bulging of Shrapnell's membrane has increased and is now bright red. Inflammation is spreading down the posterior segment. Deafness on the left side has increased, and the whispered voice can now only be heard at 3 inches. Meatal tenderness is very marked. There is definite periosteal thickening over the mastoid and slight tenderness. Other signs as before. The temperature is 99.2° F. and above normal for the first time since admission.

Operation.—Paracentesis was first performed. Schwartze's operation revealed a small granulation in the antrum, but no pus was seen. The tegmen antri was then removed. The dura was not under tension, and the surface was finely granular. The cavity was packed with bipped gauze.

December 27th: Patient has had a very good night without any narcotic. She states that aural pain and neuralgia have completely disappeared, but there is slight pain round the left eye. Diplopia as before.

December 28th: The pain round the left eye is rather worse; no return of other pain.

December 29th: First dressing, under nitrous oxide anaesthesia. The gauze wick which had been placed in the meatus was soiled with a little pus. Packing from the wound was fairly clean. She has had two good nights.

December 30th: Patient says she has been easier since the dressing was done yesterday, but still has some pain round the left eye.

December 31st: No pain in the ear or temporo-parietal region, but she has had more pain in the left eye, supraorbital region, and left cheek. Diplopia is still present, but there seems to be slight movement in the left external rectus.

January 3rd: She has had a few shooting pains in the left ear and temporo-parietal region.

January 8th: The pain round the eye has been improving gradually. She now has very little except on waking in the morning. There have been no more temporo-parietal pains. She sleeps well at night and often by day. The cavity is granulating slowly.

January 16th: There has been no pain round eye for several days, but she still wears an eye-shade in the evening as artificial light worries the eye.

January 26th: The mastoid cavity is now filling satisfactorily with healthy granulations. The patient is leaving the ward to-day and will attend daily for dressings. Eye movements are as before.

March 1st: Complete healing of the wound has been very slow, but she ceased attending daily three weeks ago, since when she has been attending Dr. Blake, who states that he first noticed return of movement in the external rectus on February 22nd. There is no diplopia now, and all movements of the left eye are as good as those of the right.

In the treatment of this case two points are especially open to criticism.

1. Paracentesis alone might have been the only operative treatment necessary, and if the pain had not been relieved by this the Schwartze operation could have been performed later. This course was not adopted on account of the excessive pain the patient was then suffering, and had suffered all the previous night. The indications for mastoid operation *per se* were slight, but it seemed unwise to risk another night of such severe pain where there was the slightest doubt as to the condition of the mastoid antrum.

2. No lumbar puncture was performed. Reports seem to agree that not only is there no macroscopic change in the cerebro-spinal fluid in these cases, but there is seldom any change to be found on pathological examination. In addition, as the hospital has no pathological department an examination of the fluid would have been difficult to obtain.

Facial neuralgia was present in the early stages of the illness, and although the operation completely relieved the severe temporo-parietal pain, the patient complained for some time afterwards of pain of lesser intensity round the left eye and in the left cheek. The anatomical explanation of the syndrome would seem to offer an easy solution to this. After piercing the inner layer of the dura mater the sixth nerve lies for a few millimetres with the inferior petrosal sinus in between the two layers of the dura mater at the tip of the petrous bone in what is known as Dorello's canal. This canal is bounded below by the petro-sphenoidal suture, above by the posterior clinoid process and petro-sphenoidal ligament, internally by the dorsum sellae, and externally by the apex of the petrous bone.[1 2] The Gasserian ganglion lies in the trigeminal impression on the antero-superior surface of the petrous bone near its apex.

The syndrome is said to be due to a serous extradural inflammation implicating the sixth nerve in Dorello's canal. Hence from the proximity of the Gasserian ganglion it would be expected that the fifth nerve involvement would not be uncommon. This involvement has been stressed by Rimini,[3] and was marked (with slight photophobia) in the case reported by Hamilton and Kerr.[4]

There was no involvement of any cranial nerve other than the fifth and sixth, and there was no homolateral retropharyngeal swelling, as occasionally occurs and was noted by Leitch.[5]

The notes of this case were submitted to Mr. G. J. Jenkins for his opinion, and I am exceedingly indebted to him for his comments. He considered the case to be a typical Gradenigo's syndrome, and he particularly emphasized the fifth nerve distribution of the pain, which he states is more common than is generally recognized. I have to acknowledge my thanks to Dr. V. H. Blake for permitting me to treat the case, for additional details in the history before admission to hospital, and for valuable criticism in the presentation of these notes.

TREATMENT OF ACTINOMYCOSIS.

BY

HUBERT CHITTY, M.S.Lond., F.R.C.S.Eng.,

SURGEON, BRISTOL ROYAL INFIRMARY.

In an article published in the *British Medical Journal* on March 6th, 1926 (p. 418), I gave an account of four consecutive cases of actinomycosis which had been rapidly cured by small doses of tincture of iodine administered in milk. I believed at the time that iodine given in this way was in a colloidal state. When milk is added to tincture of iodine a point is reached at which the mixture becomes colourless and tasteless. This result is more rapidly attained when cream is substituted for milk, and it appears that the iodine unites with the cream to produce an iodized fat.

In this connexion the observations of Dr. Warwick Preston[1] are of great interest. He records two cases of actinomycosis of the lung which improved rapidly after the injection into the trachea, for diagnostic purposes, of lipiodol—an iodized oil. A subsequent course of iodine and milk completed the cure. This suggests that various iodized fats may have a similar specific action upon actinomycosis.

Black mycetoma is a disease produced by an organism similar to the ray-fungus, and I have received from India reports of two cases which were cured by iodine and milk, and of one old-standing case of "Madura foot" which began to improve rapidly as soon as this treatment was instituted.

Since the appearance of my first article four additional cases of actinomycosis have been under my own care, all of which have been cured.

CASE 1.

A man, aged 42, in July, 1925, was operated upon at another hospital for appendicitis. The wound was drained, and one month later he was discharged from hospital with a sinus at the site of operation. In September of the same year he was readmitted, and further abscesses were drained in the abdomen and right loin. He first attended the Bristol Royal Infirmary on February 16th, 1926; he was then extremely emaciated and in constant pain. Hard masses filled the right side of the abdomen and extended across the epigastrium to the splenic region. Several sinuses were present in the right loin and the right side of the abdomen; from them there was a copious discharge of pus containing typical sulphur granules, and an immediate examination confirmed the presence of actinomyces. He was given *tr. iodi sine iodidi*, minim v, thrice daily in milk until March 6th, when he was admitted as an in-patient. By this time all his pain had vanished; he could eat anything, and he had put on nearly a stone in weight. The masses in the abdomen had almost vanished, but there was still some thickening around one abdominal scar. Three sinuses were still present, but there was little discharge from them, nor could actinomyces be identified any longer in the pus. He was discharged on March 17th.

He was readmitted in October, 1926, as three sinuses refused to heal; they all communicated, and were probably due to a deep infected ligature. They eventually closed after being injected with various substances, such as brilliant green and crystal violet.

CASE II.

This patient, also a man aged 42, was admitted to the Bristol Royal Infirmary on September 17th, 1927. Three weeks previously he had had a right lower molar tooth extracted on account of pain and swelling in the jaw. Between this time and his admission he had had numerous anæsthetics for the extraction of other teeth, the exploration of his lower jaw, and the opening of sundry abscesses of the face and neck.

On admission the whole of the right side of the face was greatly swollen; large fluctuating abscesses extended from below the right angle of the jaw to the right temporal region, and he was unable to open his mouth. The abscesses were opened freely, actinomyces was identified microscopically, and he was put on the usual treatment. On October 12th he was discharged healed. Some thickening persisted in the tonsillar region, and it was three months before this had disappeared completely. He has remained well ever since.

CASE III.

A man, aged 25, was admitted as a case of probable actinomycosis on April 4th, 1927. He had a hard swelling over the left side of the jaw, and a history of recurrent abscess formation for seven months previously. The abscess was opened and the pus examined with a negative result. He had been put on the iodine treatment, but in view of this finding, and the fact that the abscess healed rapidly, this was discontinued, and he was discharged.

He returned with another abscess in September, and this time actinomyces was identified. He was put on treatment again, and the lesion slowly healed, leaving a deep depression in the jaw where bone had been destroyed. He has remained well ever since.

CASE IV.

This case, that of a youth aged 17, was very similar to the last. He first attended the Royal Infirmary on October 8th, 1927, with an indurated swelling over the left side of the lower jaw. This soon broke down to form an abscess, the pus from which was found to contain actinomyces.

He was put on the same treatment, and his wound rapidly healed. He was last seen on December 13th of that year, but he writes, in answer to an inquiry, to say that he has had no recurrence of the trouble since that date.

A CASE OF ULCERATIVE ENDOCARDITIS OF PUERPERAL ORIGIN.

BY

E. K. MACDONALD, M.D., B.S.LOND., D.P.H.,

DEPUTY MEDICAL SUPERINTENDENT, KENDRAY HOSPITAL, BARNSLEY,

AND

G. R. MACNAB, B.SC., M.B., CH.B.ED.

THIS fatal case of puerperal sepsis is interesting because of the almost total absence of pelvic symptoms or signs, and because there were no clinical signs suggestive of heart lesions such as were found at necropsy.

Clinical History.

A primipara, aged 23, was confined in an outlying district on July 21st, 1928; the labour was normal except for early rupture of the membranes. No instrument was used, and there was no trauma. Up to about the tenth day, when the patient was reported by her mother to have had a rigor, the puerperium was normal. She got up on the eleventh day, but further rigors were reported to have occurred on the seventeenth and twenty-fourth days. On the twenty-ninth day she came to Barnsley to her mother's house, and on the thirtieth day had another rigor.

One of us (G. R. M.) was called in on the thirty-first day, and found the following conditions: the temperature was 99° F. and the pulse 120; the uterus was fully involuted, retroverted, and free from tenderness, and there was no uterine discharge. The urine was normal, and no other abnormal signs were found. The retroversion was replaced. On the night of the thirty-third day the patient became orthopnoeic, her temperature rose to 102.6° F., and her pulse to 140. On examination a gallop rhythm was found at the heart, but no enlargement or murmurs were detected. The bases of both lungs were dull on percussion, and auscultation revealed moist sounds and friction rub. An injection of atropine, strychnine, and digitaline was administered. On the thirty-fourth day we both saw the patient in consultation. She was obviously suffering from toxic absorption, but no other abnormality was found. The lungs were now resonant and free from abnormal signs. Material was taken for an agglutination test, which proved to be negative. From now on the patient had numerous rigors. On the thirty-seventh day she was admitted to hospital. On examination we found that the heart was not enlarged, and there were no murmurs to be heard. There was a reduplicated first sign at the apex and the left border of the sternum. Occasionally sibilant rales were heard in the lungs. The pelvic organs were apparently normal, except for a slight, non-offensive uterine discharge. The patient was given 25 c.cm. of antistreptococcus (puerperal) serum. She was restless that night, and on the morning of the thirty-eighth day she collapsed. She was orthopnoeic, but with stimulant treatment made a partial recovery; her temperature, however, was 107° F. She remained in a typhoid state until her death on the fortieth day. Towards the end the patient's urine was highly coloured with urates and loaded with albumin. Her temperature varied from 103° to 107° F., her pulse became uncountable, and her respiration rate varied from 45 to 75.

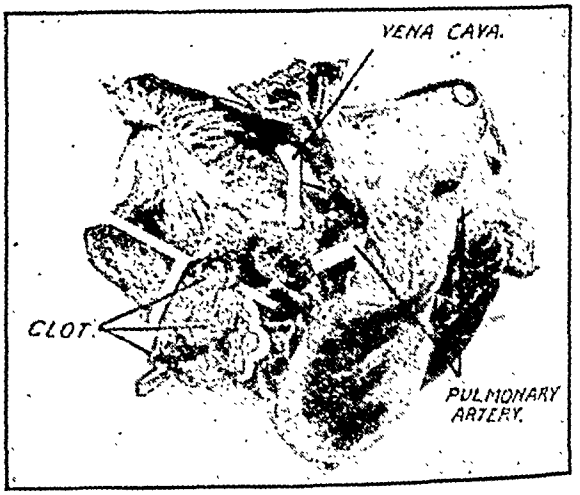
Post-mortem Findings.

On September 1st, 1928, a *post-mortem* examination was made. Apart from tumidity of the abdomen there were no external signs of disease.

Abdomen.—There were no signs of peritonitis, and the bowel, though considerably distended, was not ulcerated. The liver was enlarged, passively congested, and showed signs of cloudy swelling; there were no abscesses. The spleen was enlarged, congested, very friable, and free from abscesses; the Malpighian bodies were not visible. The kidneys were pale, the cells being in a condition of cloudy swelling; there were no signs of abscess formation. The uterus was well involuted, the mucous membrane being soft and friable, and slightly septic. The os was slightly patulous, and a recent blood clot was found in the body of the uterus. There was nothing else abnormal in the pelvis.

Lungs.—These were in a state of hypostatic congestion, and at both bases there were recent pleural adhesions to the diaphragm. There were no signs of infarct or abscess formation.

Heart.—The pericardium contained about 3 oz. of greenish fluid with some shreds of fibrin. On the anterior epicardiac surface



there was a serous patch about the size of a threepenny-piece. The heart weighed 7¾ oz.; its muscles were rather pale and flabby. The left auricle and left ventricle were normal. The mitral valve showed signs of early endocarditis, with the formation of pink nodules on its ventricular surface. The aorta and coronary arteries were healthy, but the aortic valves showed signs of endocarditis. The papillary muscles of the right ventricle were friable and inflamed. There was (as shown in the photograph) a large suppurating blood clot, weighing 126 grains and measuring 6.3 by 2.2 cm., firmly attached to the anterior cusp of the tricuspid valve. The cusps of the tricuspid valve were greatly thickened and in a state of necrotic ulceration. The right auricle and the pulmonary valve were apparently healthy, but attached proximally to the left posterior cusp of the tricuspid valve, and passing through the pulmonary valve into the pulmonary artery was a thin, recent *ante-mortem* clot, 8 cm. long, and bifurcated at the distal end.

COMMENT.

The clot attached to the tricuspid valve was wedged in the valve ring, and we considered that it was probably acting as a ball valve and had been present for two or three weeks. Of special interest were the site of the chief cardiac lesion and, apart from the reduplicated first sound, the absence of abnormal signs. At no time did the patient complain of pelvic or cardiac pain, nor could any previous history of rheumatism or tonsillar or cardiac trouble be elicited.

We are indebted to Dr. T. E. Francis and Dr. D. H. Hubbs for permission to publish this case.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

TRAUMATIC RUPTURE OF THE SPLEEN COMPLICATED BY HAEMATURIA.

THE following instance of rupture of the spleen seems worth recording in view of the masking of the diagnosis by haematuria, and the relatively slow pulse rate.

A man, aged 29, was admitted to hospital one night in a dazed condition. He had been riding a motor cycle round a bend in the road when he had skidded; he could remember nothing of the accident. There was no history of malaria, and the patient had never been abroad.

On admission he complained of pain in the left loin and in the head; the forehead was contused and there was some epistaxis. The pulse rate was 74 and the temperature 96.8° F. There was no pain, tenderness, or rigidity in the abdomen. The next morning the pain in the left loin was more pronounced and was accompanied by a swelling which extended forwards from the left kidney angle, and blood-stained urine was passed. The pulse rate was 82 and the temperature 98.2° F. During the day he began to complain of pain in the epigastrium, thirst, and dryness of the mouth. He vomited occasionally, but the vomit consisted mainly of fluids administered. The pulse rate was taken hourly during the day and ranged from 82 to 86, the volume being well maintained. Four specimens of urine were collected; the colour varied from smoky to definite red. In the evening a little distension of the abdomen was noticed.

On the following day the pulse rate was 88, but the volume remained good. The patient was still vomiting and the abdomen was somewhat more distended. The bowels having been confined since admission, an enema was given, and was followed by considerable relief. At noon the pulse rate remained at 88, but the abdomen was becoming distended again, and some dullness in the flanks was now present for the first time. It was more marked on the left side, though it could be made to shift from either side. After this the dullness and distension steadily increased, although the pulse rate never exceeded 88. The urine passed during the morning had remained blood-stained. At no time had the patient complained of pain in the left shoulder.

It was thought that the kidney had ruptured into the peritoneal cavity, and that *afternoon the abdomen* was opened by a left paramedian incision above the umbilicus. A large quantity of free blood was encountered as soon as the peritoneum was incised; this was rapidly mopped up. Examination of the left kidney area showed some swelling, but no communication with the peritoneal cavity. Blood was found to be issuing from the upper left quadrant of the abdomen, and the *examining hand* encountered a ruptured spleen. An incision across the *left rectus* enabled the spleen to be brought out of the wound. The *upper* pole was pulped and, in addition, there was a transverse wound at the level of the hilum. The pedicle was ligatured and the organ was removed.

Convalescence was uneventful save for the haematuria, which *continued* for twelve days, but gradually abated.

The cardinal signs of *splenic rupture*—namely, *abdominal rigidity*, *local tenderness*, Ballance's sign (shifting dullness in the right flank and constant dullness in the left flank), and Kehr's sign of pain referred to the left *shoulder*—were singularly absent in this patient.

Foucault[1] mentions rupture of the kidney in differential diagnosis from rupture of the spleen, and states that the latter is made apparent by the associated haematuria and lumbar swelling, both of which were present in this instance.

Gordon Watson[2] remarks that in rupture of the spleen the pulse diminishes in volume as it increases in rate until it becomes running and imperceptible. Hamilton Bailey[3] says that "when the diagnosis is uncertain a clearly recorded half-hourly pulse chart is above all things of the greatest diagnostic value."

More helpful in this instance was the dictum of Butler and Carlson,[4] who discuss nine cases of traumatic rupture of the spleen: "In all patients in whom there is a history of trauma to the abdomen, to the flanks, or to the lower chest, even if there is no visible injury or local evidence of injury, we must always be alert and not overlook the slowly developing shock, the slight distension, and the abdominal pain, not too severe, that are the early signs of rupture of the spleen."

THE CAUSE AND CURE OF MORNING SICKNESS.

MANY years ago I was treating a pregnant patient for a vaginal condition, and among other things I used a tampon of glycerin and borax (*B.P.*). When I next called on her I was greatly interested in her statement that since my previous visit she had been quite free from morning sickness. This caused me to investigate the matter, and after eliminating other factors I concluded that the cure was due to the glycerin tampon. Thereafter I made it my constant practice to treat cases of morning sickness with glycerin and borax tampons, and since that time I have never had a failure.

I mentioned this treatment at various times to my assistants, and also to my fellow practitioners, and spoke about it at the Glasgow Gynaecological and Obstetrical Society, without being able to explain why it should be successful. Recently I hit upon what I believe to be the *solution of the problem*. On reading up the subject I find that all the successful cures so far recorded have followed the opening of the cervical canal; one practitioner forced *his finger through the cervical canal*, while another employed a wide, tapered sound. The risk of these procedures was so manifest that their disuse followed. One other practitioner swabbed the cervix with a solution of silver nitrate, causing a marked improvement in the patient's condition.

I have been watching my cases recently and have observed the following facts. The vulva and vagina were turgid, swollen, and discoloured; the cervix was also swollen, and the canal was choked with the increased secretions from the *endocervical* glands. After the use of the tampons the turgidity of the vulva and vagina was greatly diminished, while the colour was much brighter and more healthy looking; the greatest improvement, however, is to be seen *in the cervix, which is greatly diminished in size*, and in the cervical canal, which is practically normal.

How does it come about that the closure or choking of the *cervical canal* should cause morning sickness? Our *surgeons could* understand it by comparing it to choked ducts such as the bile duct, or obstruction as *in strangulated* hernia; one has only to think of what happens when the Eustachian tubes become obstructed.

Technique of Applying Tampon.

A piece of Gamgee tissue 2 by 4 inches is rolled up, and tied with a length of soft crochet thread, two ends of the thread about 8 or 10 inches long are left, so that the patient may remove the pad herself. It is then inserted into the pouch of Douglas, extending at least as far as the vault, and lying in contact with the cervix. This pad can be removed after being in position for two days, and another pad can be inserted. I generally find that two pads are quite sufficient, and I have had to use four pads on only two occasions.

There is no reason why they should not be persevered with in profound cases until the sickness has entirely passed away. My experience has been that in mild cases one tampon gives so much relief that, generally, there is no necessity for a second. The most inveterate cases may require up to four, each one giving increased relief.

To sum up, in simple morning sickness one or two tampons will suffice. In hyperemesis gravidarum, or, as our American friends call it, the profound emesis of pregnancy, four tampons may be required.

Paisley. ANDREW RICHMOND, M.B., C.M.

MYXOEDEMA FOLLOWING MAMMARY HYPERTROPHY IN CHILDHOOD.

THE unusual after-history of the case about to be described is my excuse for submitting it for publication.

The patient was a perfectly healthy girl until the age of 13, when it was noticed that both breasts were rapidly increasing in size. The enlargement became so great that it was necessary to seek treatment, and she was accordingly admitted to the Pendlebury Hospital, Manchester, on April 4th, 1920. The following is a note of the condition made at the time of her admission, and for which I am indebted to the secretary of the hospital.

"There is a very great hypertrophy of both breasts, especially the right. The hypertrophy is general, diffused, and is *not a tumour*; there is no localization and all the breast tissue is involved. The breasts are *quite soft and flabby*, while here and there strands of fibrous tissue can be felt; when *the girl* stands up the right breast hangs well over the abdomen. There is no

pain, no inflammation, no glandular enlargement, and no hypertrophy of tissue elsewhere."

On April 21st, 1900, the right breast was removed and was found to weight 8 lb. 2 oz. Two months after the operation the girl menstruated for the first time. The left breast was amputated in July of the same year and weighed 6 lb. 8 oz. The patient made an excellent recovery from both operations, and for the next twenty years her health was good, except that the periods were irregular, the loss scanty, and a good deal of pain was experienced. She was married in 1917, and in the following year gave birth to a healthy male child.

About the beginning of 1922 she began to grow very stout, complained of weakness, and walking was difficult from stiffness of the knees and ankles. She thought she had "dropsy," and consulted a doctor, who, after examining the urine, assured her that there was nothing wrong with the kidneys. I saw her first in December, 1925, when she presented the typical picture of advanced myxoedema. There was no albuminuria. Treatment by thyroid extract was started at once, at first tentatively, and then pushed gradually to the limit of tolerance. The result was that the condition cleared up rapidly, and one of the most striking effects from the patient's point of view was that she menstruated regularly and painlessly for the first time in her life. She still takes thyroid extract, and three years after the commencement of the treatment remains perfectly well.

The long history of *dysmenorrhoea* suggests that a degree of hypothyroidism existed, at any rate from *puberty*; while it is more than likely that the condition of the breasts occurring at this time may have had its origin in some derangement of the endocrine system.

Reports of Societies.

GENERAL PARALYSIS OF THE INSANE.

THE Sections of Psychiatry and Neurology of the Royal Society of Medicine combined on February 12th and 14th for a discussion on the prognosis and treatment of general paralysis of the insane. On the first evening Sir MAURICE CRAIG presided, and on the second evening Mr. DONALD ARMOUR.

Dr. W. H. B. STODDART, in opening, remarked that it would be interesting to know in what proportion of cases a remission occurred when the disease was allowed to run its natural course. In the report of the London mental hospitals for 1926 it was stated that during the three years previous to the introduction of malarial therapy only 2.6 per cent. of the 227 cases of general paralysis were improved. During the first decade of the present century the speaker was in the habit of giving hexamine to general paralytics, with the result that remissions occurred in about 25 per cent. of the cases. The drug acted best when the patients were receiving a certain amount of alcohol in the form of brandy at the same time. General paralytics treated with hexamine had no apoplectic or epileptic seizures, and their lives were prolonged. The ordinary antisyphilitic treatment with mercury, iodide of potassium, or salvarsan was of no value, because these drugs could not enter the cerebro-spinal fluid. Some attempts had been made to introduce salvarsanized or mercurialized serum into the cranium, but, on the whole, the clinical amelioration appeared to have been very slight; some such phrase as "no untoward sequels" was the most usual in the reports. With regard to tryparsamide, this was said to have been found of special service in America, but there was a risk with this treatment of producing optic atrophy. On the subject of pyrexial treatment, the question had been raised whether it was better to transfer the malarial blood from one patient to another or to employ the mosquito as intermediate host; so far as he was aware neither method had an advantage. With both methods there were patients who did not contract malaria, or the malaria disappeared after the patient had had six or seven rigors. Contraindications to malarial treatment could all be classed under one heading—namely, a poor general condition of the patient.

Sir JAMES PURVES-STEWART said that the term "general paralysis of the insane" was a clinical label some fifty years old; he suggested the name "progressive syphilitic encephalitis" for common use. Until a few years ago the disease appeared to be resistant to the most assiduous antisyphilitic treatment. The outlook had changed somewhat for the better during the past six or seven years. No true specific therapy was yet available, but a wave of therapeutic activity had appeared, and three lines of medication had been *on trial: pyrexial* treatment, *especially malarial inoculation; tryparsamide; and* salvarsanized *serum*, by itself or following a previous pyrexial course. Evidence that true specific treatment had not yet been attained was afforded by the fact that, despite occasional dramatic improvements, the serological reactions in the blood, and still more in the cerebro-spinal fluid, often remained positive; so long as this was so the disease could not be regarded as at an end. As a matter of clinical experience, benign tertian malaria had proved the most convenient *method of inducing* artificial pyrexia. Now and then a patient was found resistant to malarial inoculation, but an efficient series of pyrexial reactions could usually be produced by other means. The results of pyrexial treatment had been variously appraised. It certainly modified clinical symptoms, but it was not devoid of risk; he had known five patients die of cardiac failure during or shortly after a course of malarial injections. Many observers were content if the outstanding mental symptoms cleared up. In America good results had been obtained by tryparsamide treatment in a number of instances, and salvarsanized serum yielded comparatively favourable results. In order to supplement the clinical improvement achieved by the pyrexial course he had himself followed up malarial treatment with intracisternal injections of salvarsanized serum in the hope of securing serological results. He presented a series of 24 patients so treated, dating from 1922 to 1928, but mostly 1923 to 1925. Ten of these had remained perfectly well, clinically and serologically, for periods of from two to five years; 4 had improved for two or three years and subsequently relapsed; 2 others had slightly improved. He described one case, seen as a certified patient who was grandiose, incoherent, and had dysarthria. Malaria was first given, but the condition of the patient remained exalted and dysarthric. Salvarsanized serum was then tried, and the patient became mentally alert, the dysarthria being doubtful. *In June*, 1926, two years after the date when first seen, he was at home again, released from certificates; in January, 1929, he was still mentally normal, and had complete negative serological reactions in the blood and cerebro-spinal fluid. The speaker insisted that the standard of recovery should not be the mere remission or even the disappearance of clinical symptoms, but should also comprise the disappearance of the characteristic serological reactions.

Dr. J. BRANDER (Bexley) said that in general paralysis it was the diagnosis which was most likely to provoke differences of opinion. While acknowledging freely the great assistance to be derived from the laboratory both in diagnosis and control of treatment, he believed that serological examinations had introduced into the diagnosis of this disease an added source of confusion. There had been for some years a tendency to associate under the term "general paralysis" both the classical forms and the so-called neurological or mixed types, mostly on the basis of the serological findings, which might be very similar in the two groups. In mental hospitals the neurological type used not to be classified as general paralysis, but was called insanity with a gross brain lesion. Such patients responded in varying degrees to treatment, and were considered to have a much less grave prognosis, especially with regard to life, than was the case in general paralysis strictly so called. It was obvious that very different statistical results might be obtained according to the relative proportions of the two groups in a series. It was important from many points of view to discriminate between original general paralysis and the heterogeneous group of *symptoms associated* with it. The suggestion had been put forward that the character of general paralysis was changing, that it was less malign; but he had examined in detail the records of his own and his colleagues' cases for 1910–14 and for 1920–24, and found no difference in the character of the cases as between the two periods, except that the maximum incidence in the later period was in the age group 40–45, whereas in the earlier period it was in the age group 35–40. Instead of assuming a change in type he thought one should guard against any ready change of diagnostic standards. The speaker went on to refer to cases treated at Bexley with malaria. Since

1923 the number of patients with general paralysis so treated was 102; of these, 35 had recovered or very much improved, 16 had improved, 26 remained unimproved, and the remainder had died. Some patients who were apparently in a very advanced stage recovered to a remarkable degree, while some seemingly early cases went steadily downwards. The duration of symptoms prior to treatment, however, varied directly with the prognosis; 9.9 months was the average duration of the total series, compared with 6.4 months in those recovered sufficiently to be discharged. Among the discharged cases, 80 per cent. of those which it had been possible to follow up showed a decreased strength of Wassermann reaction in the cerebro-spinal fluid, 10 per cent. an increased strength, and 10 per cent. no change. Again, 50 per cent. showed a decreased strength of the reaction in the blood, and 45 per cent. no change. It would appear that malaria in itself was able in many cases to initiate the elimination of the virus of general paralysis, but if the disease process had attained a certain degree of severity there might continue to be manifest in the patient symptoms of progressive development not now of an actively syphilitic nature.

Dr. E. D. MACNAMARA (Charing Cross Hospital) held that malarial therapy offered hope for general paralysis, especially if combined with antisyphilitic treatment, always provided that it was only given in those cases in which the general health was such as to make it seem likely that the patient could bear up against the severe illness inflicted upon him. Records of remissions without any particular treatment were common even for such long periods as seven or eleven years. General paralysis might be long drawn out in its march; the longest case of which he had been able to find a record went on for twenty-five years. Therefore one should not be too sanguine about remissions, or lightly attribute them to a particular treatment. Periods of remission, again, might be very brief though apparently complete. The spirochaete had been found in the cortex of patients who had recently undergone malarial treatment. It should also be noted that in cases the earlier stages of which had been well or ill treated according to current practice, mental impairment and abnormal signs had been observed later, together with serum and cell changes. These were stages at which the application of malarial treatment was encouraged, but apparently the phase might last for years, and might disappear under antisyphilitic treatment or other forms of treatment, or the mere lapse of time. The moot point was whether the general assumption was not too embracing, and whether many such cases were not compatible with a meningo-vascular disease which would never, in the nature of things, become general paralysis at all.

Dr. F. H. STEWART (Cheddleton) described a modification of malarial treatment which minimized the suffering and danger to the patient. During the last two years he had treated cases by inoculating the patient in the usual way, and, after one or two rigors, stopping the attack by a thorough course of quinine. The general paralysis was generally affected by this short course of malarial treatment. After the quinine the patient was also treated actively with tryparsamide. In two months the same cycle was repeated, and repeated again until the patient had either recovered or it was clear that no further improvement was to be expected. Of 22 cases treated on this plan, 6 had been cured or greatly improved, 4 improved, in 7 the disease had been arrested, in 2 there had been no improvement, and 3 had died.

Dr. G. DE M. RUDOLF (Cane Hill) declared general paralysis to be a disease in which it was almost impossible to say that the patient had recovered; untreated cases had been known to undergo well-marked remissions. No recovery could be claimed unless the patient had shown a good remission up to at least the average age of death for the sex, and had died of some other complaint. He had seen cases previously treated with malaria become apparently normal clinically, but retain well-marked serological reactions; he had also knowledge of patients who had remained typical general paralytics, but with a normal spinal fluid. One patient after malaria remained euphoric and grandiose, but developed a completely negative cerebro-spinal fluid which later again showed positive findings, the clinical condition remaining unchanged. After referring to the report of a committee of members of the London County Mental Hospitals Service on the value of malaria, published in 1926 (*British Medical Journal*, ii, 1926, p. 603), the speaker gave his own personal statistics. His experience of malaria concerned 191 cases, some of which received arsenic in addition to malaria. Of the total, 31.4 per cent. had been discharged, and of the 83 cases treated with malaria alone 37.1 per cent. had been discharged. The highest discharge rate was among patients under 40, those with less than a seven months' history, and those in good physical health.

Dr. C. C. WORSTER-DROUGHT (West End Hospital for Nervous Diseases) gave an account of treatment by malarial infection followed by a course of novarsenobillon. He dealt only with cases which had been treated in 1923–24. No case was accepted unless, in addition to clinical manifestations, the Wassermann reaction was positive in both the blood and cerebro-spinal fluid. Of the 35 patients treated in the period mentioned, 20 per cent. were still at work and useful members of society; 50 per cent. might be said to have improved in the sense that they remained more or less the same, the progressive deterioration having been arrested; 20 per cent. had been admitted to mental hospitals or had died; and 10 per cent. could not be traced. He agreed with Dr. Rudolf in thinking that though the Wassermann reaction became negative this was not necessarily a criterion of the patient's improvement. With regard to mode of infection, he preferred blood transmission; the rigors developed as a rule more rapidly, appeared less exhausting to the patient, and were more easily controlled.

Dr. A. A. W. PETRIE (Banstead) gave an account of the treatment of general paralysis by relapsing fever, the material being obtained from the blood of mice infected with *Spirochaeta duttoni* and injected into the abdominal muscle. Of the 26 cases so treated, all of them having positive Wassermann reactions in the blood serum, and all but one positive reactions in the cerebro-spinal fluid, the figures prepared within a year of treatment showed 7 discharged improved, 5 with some improvement, 9 unchanged, 2 worse, and 3 dead. Of the cases which showed some improvement, a review after the second year proved that 2 had relapsed and 1 had died, but in the other 2 there was distinct retardation of the progress of the disease; while 3 of the 9 who had shown no change now showed retardation. The infection had not proved dangerous, and in 2 cases where pyrexia seemed likely to persist the giving of novarsenobillon appeared to check the trouble. The speaker also described 11 cases of injection with saprovitan, but the results were disappointing. Between 50 and 100 cases, some of them general paralysis, had been subjected at Banstead to inoculation with milk, 10 c.cm. of milk solution being injected into the buttock muscles. This appeared to turn on the question of sterility. Injection of sterilized samples usually produced no reaction of temperature, but injection of samples which, though brought to the boil or pasteurized, still contained saprophytic bacteria, produced temperatures of 102° and 103°, without, however, abscess formation or other evident sepsis. It seemed probable that the results claimed for this method were mainly due to the reaction to organisms which still remained in the injected fluid, and not to a protein reaction.

Surgeon Rear-Admiral E. T. MEAGHER, R.N., who reopened the debate on the second evening, gave an account of a survey which he had made of the cases treated by malaria in the mental hospitals of the country and those not so treated. Of 97 mental hospitals, 56 had not so far practised the malarial treatment of general paralysis. Taking the years 1923 and 1924, his figures showed that of the patients treated with malaria among the direct admissions for general paralysis during those years, 56.4 per cent. were still alive, whereas of the untreated cases only 13.4 per cent. remained alive. The inference, whatever test was applied, was that the treated had done better than the untreated. Of 438 cases treated to the end of 1924, 134 had been discharged, and 108 of this number remained discharged. He had made personal visits to the discharged patients, and he could affirm that 77 of them were able to follow their usual avocations, 10 were mentally fairly well,

but fit for only little work, 10 were degenerating, and 11 could not be traced. He was impressed in many cases by the attention to dress and appearance which these discharged patients showed; their good memory; and the fact that their grandiose manner had disappeared. He had been convinced that malarial treatment was of value in extending life, in improving the physical and mental state, and in allowing some 20 per cent. of patients to resume a normal existence.

Dr. THOMAS TENNENT gave an account of some experiments in the intravenous injection of tryparsamide; out of 50 patients, 16 showed good remission and 13 others moderate remission. His conclusion was that tryparsamide was a valuable drug, the action of which was assisted by combining it with fever therapy, malaria being the safest form.

Dr. J. G. GREENFIELD (National Hospital for the Paralysed and Epileptic) commented on one or two cases within his observation in which the crisis of malaria had been so severe in patients already weakened by disease that they had succumbed more or less directly to the malaria; the majority who had died had done so as a result of lung complications, occurring mostly in the winter. A striking fact was the rapid disappearance of spirochaetes from the brain in general paralysis after malarial treatment. The changes in the brain included a very great increase in inflammatory reaction occurring almost immediately after malarial treatment had started; it was not surprising that when there was this acute encephalitis with malarial infection there was a tendency for the patient to die from concurrent infection. He emphasized the need for reinforcing malaria with salvarsan. In the early days there was a tendency to think that malaria did the work by itself but the evidence afforded by pathological examination had rather shown that the disease in the brain changed from the type which it was customary to find—the degenerative changes of general paralysis—to the changes associated with acute cerebral syphilis, and, of course, this had to be treated by salvarsan just as in any other case of syphilis.

Dr. D. NABARRO described the treatment given at the Children's Hospital, Great Ormond Street, in cases of congenital syphilis, quite a number of which showed involvement of the central nervous system. The symptoms encountered in children were, of course, different from those in adults suffering from general paralysis; they usually included fits and progressive mental deterioration. Methods had been adopted of treating these patients with the object of rendering the spinal fluid normal—namely, malaria and intracisternal injections of salvarsanized serum. Malaria had been given in 13 cases of congenital neuro-syphilis, only 5 of which were cases of juvenile general paralysis of the insane. No striking improvement had occurred, either clinically or serologically, in most of these cases. He was inclined to think that the benefit of malarial treatment in neuro-syphilis was not great, and that more marked benefit followed intracisternal injections.

Dr. HANS DEUTSCH (St. Louis) gave an account of the technique employed in a clinic in which malaria was always inoculated from patient to patient; if the patient did not react to the ordinary subcutaneous inoculation an intravenous injection was given. Malaria alone had never been given during the last few years, but was followed by the usual course of salvarsan. A remarkable effect was the change in the glia cells, which returned to normal. It was impossible to speak of cures, but merely of remissions, because nervous tissue would never regenerate.

Dr. GLEN DUNCAN (Severalls) reported 41 cases of general paralysis treated by malaria; all were fully investigated by routine diagnostic methods. The mortality was fairly high, 7 out of the 41 dying within two months of inoculation. In 20 the results were good, in the sense that the patient had so far recovered from his mental symptoms that he could no longer be detained under certificate. The average duration of symptoms in the patients with whom a good result was obtained was twelve months, which, curiously enough, was rather longer than the average duration in cases in which good results were not obtained.

Dr. W. D. NICOL (Horton) said that the ideal thing in the selection of cases was to get the patient as early as possible, but advanced cases had shown benefit from treatment; the obese type reacted badly. At Horton patients had now been treated for just over four years, and it had been found extremely useful to give small doses of quinine; this tended to reduce the mortality. At Horton the method of mosquito inoculation had been invariably practised. The results in the first 100 cases showed that 50 per cent. of the manic and grandiose types had remissions; about 35 per cent. of the depressed type did well; but the simple dement type, which was by far the largest group, did badly, only about 12 per cent. remitting.

Dr. KUHN (New York City) thought it justifiable to say that where there was no defect in the intellectual functions the diagnosis could not be made with any certainty on positive serological findings. The cases which showed defective intellectual functions could be divided into two groups—one essentially delirious, and the other non-delirious, but showing progressive deterioration. Delirium, however, was not always an acute florid episode, though it might be this at times, and between this and the slow deteriorating state there were all gradations. He believed that true deterioration was a stage which was reached only as a result of long and slowly progressive cortical damage; but many paretics and many neuro-syphilitics who were not paretics showed one or more delirious episodes. It was not always easy to tell whether one was dealing with a delirious state or with a deterioration. Dr. Kuhn also contributed some remarks on the treatment of the disease with arsenicals.

The two openers briefly replied. Dr. STODDART concluded from the discussion that of all the treatments devised for the disease that of malaria had the best record, but that some reinforcement was necessary, though the means suggested for reinforcement were not as yet, to him, very convincing. He was inclined in the future to follow a suggestion made by Dr. Nicol to use the quartan malaria instead of the tertian. Perhaps some of the erroneous diagnoses were due to over-importance being attached to serological tests. He now saw that treatment by occipito-atlantoid puncture seemed to have justified itself. Sir JAMES PURVES-STEWART reiterated his belief in the efficacy of occipito-atlantoid puncture, and described the method by means of a diagram. He further stated his faith that when an unfortunate victim of this disease had sustained serious damage to his vital cerebral and cell constituents no good purpose was served by efforts to keep him alive.

OSTEO-ARTHRITIS AND CHRONIC RHEUMATISM.

Two Sections of the Royal Society of Medicine last week dealt on successive days with the above general subject, in the one case from the point of view of spa treatment, and in the other from that of electrotherapy. In the Section of Balneology the chair was taken by Dr. KERR PRINGLE, and in that of Electro-Therapeutics by Dr. J. E. A. LYNHAM. One or two speakers contributed similar remarks to both discussions.

Dr. R. G. GORDON (Bath), in opening the first discussion, which was on osteo-arthritis, said that this condition was not a clearly defined clinical entity, for it might appear as a disease *sui generis* or as a terminal phase in other forms of arthritis. Infection did not seem to play a direct part in its pathology, though it might be a contributory cause of its more direct precursors. These seemed to be strain and failure of adequate circulation through the joint. The strain might be sudden in the form of injury, or gradual, owing to postural defects; it was significant that the lower limbs were more affected than the upper. Its correlation with coxa plana in children was striking, especially as the latter often passed unrecognized. Defective circulation caused impaired nutrition and degenerative changes, and when pain by muscular spasm did not stimulate artificial protection and splinting of the joint, the destruction might be very severe. Pain varied considerably in osteo-arthritic joints, and this might be related to the nutrition of sensory nerve-endings. Deformity might be increased by muscles and ligaments finding new and abnormal attachments and exerting unaccustomed traction. Treatment must be directed to preventing strain and improving the nutrition of the joint. For the first, properly fitting splints were most useful; for the second, heat associated with well-

considered massage to the muscles rather than to the joint. Theoretically surgery must have a wide field in treatment, but practically this was not so, since the patients seldom could stand severe operations. Sulphur preparations did some good in view of the interference with sulphur metabolism found in this condition.

Dr. J. A. THOMSON (Harrogate) gave an account of the radiographic appearances of the affected joints, and displayed on the screen a large number of radiographs of various joint conditions, giving his interpretations of them. An incidental point was that the presence of osteophytic growths in women was quite rare, and he had seen two cases only. The radiograph, in Dr. Thomson's opinion, was more an indication of the patient's resistance than of the disease. He considered that the plane which radiography had now attained entitled it to a place in the laboratory study of the origins and course of the processes of disease.

Professor TOM HARE gave an account of the chemical estimation of synovial fluid and blood serum of horses affected with chronic arthritis.

Dr. HENRY COHEN spoke in amplification of the same subject from the clinical side, and went on to take up some of the points raised by Dr. Thomson regarding radiographic changes. In Dr. Cohen's view the radiographic changes were not specific for osteo-arthritis; similar changes were found in the early stages of gouty disease of joints. What struck him as a clinician was that not infrequently the radiographic changes were most marked in the hip of which the patient complained less. Too much reliance must not be placed on radiographic changes; early clinical changes, particularly rigidity of the joints, were an indication of something wrong.

Dr. G. E. VILVANDRE defended the absolute value of radiography in osteo-arthritis. The condition was a definite entity, which by means of radiographs could be shown thoroughly well.

Dr. PHILIP FIGDOR believed that osteo-arthritis was always a traumatic condition, and should be treated as a local condition just as much as a fracture. By "traumatic" he meant that in all these cases there was injury, stress, or strain. He favoured treatment by means of diathermy, as being the only form of electrical current which the administrator could direct.

Dr. J. F. BRAILSFORD suggested that the occurrence of osteo-arthritis in abnormal joints was most likely due to increased and abnormal strain to which the deformity subjected them. It had been stated that when changes were evident in radiographs damage to the articular surface was so severe that little improvement could be seen in subsequent radiographs after treatment; on the other hand, the changes shown on the radiograph were typical of the condition and therefore most valuable in differential diagnosis. One frequently saw patients who were complaining of pain in a joint or joints which may have commenced without definite injury, though as a rule there was a history of excessive and strained movements. The radiographs showed no abnormal change, but the removal of a focus of sepsis caused the condition to clear up in a phenomenal manner, though it had failed to respond to other forms of treatment. Failure to locate and remove the toxic focus resulted in the occurrence of insidious destructive changes in the joints. Patients frequently experienced long periods of comfort between bouts of pain, and probably on this account failed to subject themselves to active treatment. Only when there were limitation of movement and marked osteo-arthritic changes did they first submit themselves to radiographic examination. Generally the pain in the early stage was more severe than in the later, when the most marked feature of the condition was limitation of movement. The radiographic evidence suggested that the lesion was caused by the action of a toxin on damaged or strained cartilage and bone.

Mr. WHITECHURCH HOWELL, as an orthopaedic surgeon, thought that the earliest sign of osteo-arthritis of the hip was trauma, followed as a rule by synovitis of the hip, but this the patient often regarded as trivial, and did not seek advice. If only cases were brought under treatment earlier much more could be done for them. Osteo-arthritis of the shoulder he regarded as very prevalent; it was often overlooked. He illustrated the advantage of fixing the arm well above the patient's head, instead of strapping it to the front of the body; by the former method a free range of movement would eventuate.

Dr. KERR PRINGLE insisted that osteo-arthritis was not a local disease, but a general disease, with local manifestations. He also criticized the quality of the radiographs which patients brought with them; often a fresh set had to be taken, not only to ascertain the extent of the damage, but to prove to the patient that disease was present.

Dr. R. G. GORDON, in reply, could not quite agree with Dr. Cohen that all stiffness of joints was necessarily a sign of osteo-arthritis; there were many stiff joints in which the more grave condition did not exist. While agreeing that diathermy was a valuable adjuvant, he hoped the Section would not be led away into thinking that it was the treatment for osteo-arthritis.

Electrotherapy in Rheumatic Disorders.

Dr. CHARLES W. BUCKLEY (Buxton) opened this subject with some account of spa electrotherapy. Where the waters at spas were only used internally electrotherapy was largely applied, but where a bath technique had been developed upon the results of which the fame of the spa was based, electrotherapy was less popular. Of the various methods he had found ionization of most value; it was the action of the constant current on the tissues, not the nature of the ions used, that produced the most effect. Diathermy had given good results in his hands, especially in spondylitis deformans and arthritis of the sacro-iliac and hip joints, or where deeper penetration was required than could be obtained with certainty by means of ionization. Chronic arthritis associated with much muscular wasting called for faradism or galvanism to the muscles. The static treatment and the older forms of high frequency had proved disappointing in his hands. The high candle-power electric lamp was very effective, especially in fibrositis of the back or shoulders and in sciatica. Rheumatic subjects appeared often to be hypersensitive to sunlight rays, and long exposure to the sun was frequently followed by increase in pain and stiffness. He had seen good results from deep ray therapy in two cases of spondylitis deformans.

Dr. F. D. HOWITT said that chronic rheumatism did not kill, and for that reason it had escaped until recently the medical attention it deserved. No one cause would explain all rheumatic conditions. Among the predisposing factors climate played an important part. Treatment resolved itself into two parts—namely, arrest and cure of the disease, and the correction of the results of the disease. The fact that removal of obvious sepsis in many cases did not give amelioration of symptoms might be explained by the fact that the organism was lodged in various parts of the body in sufficient quantity to produce resensitization. He thought the beneficial results obtained by electrotherapy and actinotherapy were attributable to the application of heat, elimination of waste products, and stimulation of the skin.

Dr. M. B. RAY discussed the question of accessory treatments at spas. There had been an increasing tendency to supplement the natural resources of spas by recourse to methods which at first sight might seem superfluous. He proceeded to justify by an interesting argument based on the theory of disease the combination of spa treatment with physical and electrical methods. He also stressed the function of the skin as the principal adaptive organ of the body. By the judicious use of biochemical measures the adaptive resources of the skin might be stimulated and reinforced.

Dr. AGNES SAVILL gave a description of some cases which she had been able to watch over a long period. One was a young woman who had developed a widespread arthritis, and finally went to Austria, where she was put on diathermy and a diet consisting of sweets, cakes, bread, and water. She was worse on her return, but by a readjusted diet, in which the protein allowance was made adequate, and very cautious administrations of ultra-violet radiation, with diathermy for twenty minutes four times a week, she steadily improved, and had been undoubtedly saved from a serious rheumatoid arthritis.

Dr. E. P. CUMBERBATCH said that it was now established that a number of cases of arthritis in women were due to an infection which arose from a primary focus in the cervix uteri. It was now the custom in his department at St. Bartholomew's to expose the cervix uteri, and if chronic infection was discovered, not necessarily gonococcal, the cervix was subjected to diathermy, and in about 70 or 80 per cent. of the cases the arthritis was brought to an end. He and his colleagues also believed that the arthritis due to disturbance in the ovarian endocrine function was closely related to disturbances of menstrual function, and these cases had been treated by applying diathermy to the ovarics.

Dr. KERR RUSSELL said that recently he had had the privilege of visiting a number of treatment centres abroad, and in no single case did he see ionization treatment administered, but in a well-known clinic in Amsterdam he saw fifteen ultra-violet lamps in constant use. He considered ultra-violet radiation to be a very useful adjunct in the treatment of rheumatic conditions.

Dr. G. B. BATTEN suggested that the static wave current (the Morton current) was the best form of electrical vibration to be obtained. If applied properly, it not only attacked the whole muscle, but all the fibres and cells of the affected parts.

Dr. A. E. BARCLAY asked what had happened to the classification of rheumatism. Were they all treating rheumatism blindly, or had they come to the conclusion that rheumatism was an end-result?

Dr. C. A. ROBINSON, Dr. Cumberbatch's colleague, in reply to a question as to how diathermy was applied in the male in the corresponding condition to that of which Dr. Cumberbatch had spoken, said that they had been led to treat the cases of arthritis associated with amenorrhoea in young women by the results they had obtained in heating the prostate in men. In selected cases striking results were obtained in the arthritis of men by heating the prostate with diathermy.

Dr. ALASTAIR MACGREGOR remarked on the ease with which bruising took place in these subjects when there was infection of the colon.

Dr. BUCKLEY, in replying, said that a great deal of importance must be attached to splinting in the acute forms, but if splinting was adopted rigidly, as it frequently was, the condition might be made worse. With regard to ultra-violet radiation, this might be an advantage in rheumatism, but with a patient seen for a limited time it was a great mistake to subject him to a treatment of doubtful value, particularly when one was surrounded by apparatus which one knew to be efficient.

CALCIUM METABOLISM AND TETANY.

At a meeting of the Aberdeen Medico-Chirurgical Society on February 7th, with the president, Professor ALEXANDER LOW, in the chair, two papers on closely associated topics were read, one on calcium metabolism by Dr. ALEXANDER LYALL, and the other on infantile tetany by Dr. JAMES A. STEPHEN.

Dr. Lyall dealt with the subject mostly from the aspect of the calcium content of the blood and its alterations in experimental and pathological conditions. He described briefly the principle of the method of estimation of the calcium of the blood. The serum from clotted blood was usually taken for this purpose, and the calcium precipitated as the oxalate. This precipitate was dried and converted to the carbonate, and the amount of calcium estimated by dissolving the precipitate in standard phosphoric acid. Dr. Lyall said that the calcium content in health was very constant—about 10 mg. per 100 c.cm. of blood, with from 9 to 11 mg. as its widest limits. The actual formation of the calcium was not known; it probably existed partly as the chloride, phosphate, and the bicarbonate, and partly as a colloidal calcium phosphate stabilized by the blood proteins. About 60 per cent. of the total was present in a diffusible form, while the remainder was bound to protein and non-diffusible; part of the diffusible fraction was ionized. Dr. Lyall discussed the experiments of Percival and Stewart showing the existence of a diffusible fraction by the injection of calcium containing fluid and calcium-free fluid into the peritoneum of the cat. The fluid recovered always contained about 6 mg. calcium per cent. He also demonstrated a sample of fluid from the pleural cavity in a case of polyserositis. The fluid contained 7 mg. of calcium per cent., while the serum content was 9.2 mg. per cent. The speaker then detailed in tabular form the conditions under which alteration in the amount of blood calcium might occur.

A. Calcium decreased.
  1. Experimental:
    (a) Parathyroidectomy.
    (b) Phosphate injection.
    (c) Ovarian extract injection.
  2. Pathological:
    (a) Tetany { Infantile. / Adult ... { Nephritic acidosis. / Alkalosis.
    (b) Rickets.
    (c) Nephritis with oedema.
    (d) Long-standing sepsis.

B. Calcium increased.
  Experimental:
    (a) Administration of calcium { by mouth. / intravenously.
    (b) Administration of parathyroid extract.

C. Changes in the ratio of diffusible fraction.

Dr. Lyall illustrated his remarks by describing the chemical findings in a case of alkalotic tetany due to persistent vomiting, and in two cases of tetany occurring in the uraemic state where the blood calcium had fallen as low as 5 mg. per cent., with a concurrent increase in blood phosphates to 25 mg. per cent. Discussing the recent work on the effect of calcium or parathyroid administration on the production and resolution of effusions, Dr. Lyall said that the experimental findings did not wholly justify their employment clinically, and that therapeutic use of these substances was in danger of advancing ahead of experimental ratification.

Dr. Stephen followed with a short paper on infantile tetany, and dealt chiefly with the symptoms, diagnosis, and treatment. Photographs were exhibited illustrating the carpo-pedal spasms in a case of "manifest" tetany, and showing Trousseau's sign induced in a case of "latent" tetany by pressure on the upper arm. In discussing the etiology and the association of tetany with rickets, he referred to Professor J. J. R. Macleod's work on this subject, where three theories were discussed: (1) the intoxication theory; (2) the calcium deficiency theory; (3) the theory of disturbed acid-base equilibrium. The conclusion was reached that the theory of calcium deficiency was supported by much unequivocal experimental data and the final isolation of the parathyroid hormone (Collip) definitely associated the parathyroids with calcium metabolism. Macleod, however, had summed up by stating that of the three theories no single one was sufficiently comprehensive to explain all forms of tetany, and the tetany syndrome need not necessarily be regarded as an entity. It was a manifestation of neuro-muscular excitability. Dr. Stephen then detailed the treatment of tetany, pointing out that the therapeutic indications were twofold: (1) to remove the constitutional abnormality by regulation of the diet—mainly on antirachitic lines; and (2) while the abnormal excitability lasted, to ward off and relieve the more serious of the nervous attacks. Breast milk was advisable for young children, and the amount of cow's milk, especially its fat content, should be reduced; skimmed lactic milk had been found useful. For older children additions should be made to the diet of foods rich in calcium, such as cabbage, turnip, and oatmeal in the form of vegetable purée. Cod-liver oil should be given in all cases. The chief hygienic measure was to have the child nursed in the open air and sunlight as much as possible; where this was impracticable ultra-violet light could be applied. The medicinal treatment consisted in the administration of acids given as hydrochloric acid, calcium chloride, or ammonium chloride, and for the spasms chloral hydrate by the mouth or the rectum. He also mentioned that Clendening had recommended in severe cases the intravenous injection of calcium salts or Collip's extract of parathyroid gland—5 units per kilo of body weight for each milligram of calcium rise desired, but that he had had no personal experience of this treatment.

Reviews.

TEXTBOOKS ON UROLOGY.

UROLOGY[1] by EDWARD L. KEYES, professor of urology at Cornell University, is the lineal descendant of *A Practical Treatise on the Surgical Diseases of the Genito-Urinary Organs*, published in 1874 by W. H. Van Buren and E. L. Keyes. Like it predecessor it is based almost entirely on clinical knowledge. The author in his preface admits to "a certain impatience with second-hand knowledge," and has drawn almost entirely on a store of personal experience accumulated during many years of urological work. The usual anatomical, embryological, histological, and bacteriological chapters that are found at the beginning of most textbooks of urology have been omitted, and the reader is brought immediately to the subject of the physical examination of the patient. Following this are chapters on genito-urinary instruments, cystoscopy, radiography, and renal function tests. Some may consider that the author is over-dogmatic, but the majority of readers will welcome the precise nature of the instructions contained within the covers of this book. Only those methods of treatment of which the writer has direct personal knowledge are described. This, of course, results in certain omissions; for example, in the chapter devoted to the treatment of strictures no mention is made of the use of the Kollmann in dilatation, or of the radical operation of excision. But in a book of this kind such omissions are inevitable, and the disadvantage of their occurrence is more than outweighed by the advantage of knowing that the methods of treatment that are described are endorsed by the personal experience of such an authority as Dr. Edward L. Keyes. Textbooks are too often constructed out of textbooks, mixed with a small amount of original experience. Statements which appear in one are served up in another without sifting the corn from the chaff. Dr. Keyes has no patience with such methods. Thus, of the trabeculation found in tabetic bladders he writes, "Many cystoscopists have described types of bladder trabeculation as characteristic of the tabetic bladder. None of these descriptions has fulfilled its purpose. The paralysis does cause a trabeculation more marked than one would expect to find as the result of a given retention. But this difference is in no way characteristic. The only cystoscopic evidence of bladder paralysis is the open internal sphincter." What the average surgeon asks for when he consults the work of an authority is for clear instruction as to the right method of treatment. He does not wish to be told that certain methods may be of use or that this or that authority has reported favourably of another. The author of *Urology* tells him in no uncertain voice what he should do. What could be more precise than his advice on operations for injury to the kidney? "The next question that arises is the viability of the kidney. If more than one-third of the kidney appears to have lost its blood supply nephrectomy will be required; if less than one-third the necrotic portion may be excised, or if it is small left undisturbed. There is little value in suturing ragged tears in the kidney substance, a tube drain will be left in the loin." Even in chapters dealing with troubles concerning which our knowledge is inexact and often highly theoretical the same clearness of expression is maintained. The author would probably be the last to lay claim to any special knowledge of psychology. Nevertheless the average reader will obtain more insight into functional derangements of the sex organs from a perusal of chapter xiv than after copious reading in special volumes dedicated to that subject. Every practitioner who deals with sexual disabilities knows how difficult it is to handle these troubles. Each specialist has his own favourite formula for treatment. Their numbers attest their fallibility. "Try," says Dr. Keyes, "to make hygiene and psychology dominate over practice. I never guarantee success from local treatment. I attempt to plumb the patient's sexual ideals, habits, and history before beginning local treatment." The chapter on derangements of the male genital organs contains very few of the technicalities of psychology, but a great deal of common sense. *Urology* is a book based on the principles and practice of a lifetime. Its strongly individualistic note is not the least of its merits.

Another *Text-Book of Urology*[2] from America is by DANIEL N. EISENDRATH, a Chicago urologist, and HARRY C. ROLNICK, associate urologist, Mount Sinai Hospital. The book has been expressly written for the general practitioner and the medical student. The authors state that in the numerous works on this subject in current use there is a tendency towards over-specialization. The surgical side is stressed at the expense of the study of the genital tract and of venereal diseases. They aim at remedying this defect by publishing a book which deals with diseases of the male genitalia in as thorough a manner as possible. If this is the main object of the work it may be at once conceded that the authors have achieved their desire. The chapters on the genitalia and their diseases are undoubtedly the best in the book. Common conditions, such as epididymitis, vesiculitis, enlargement of the prostate, and varicocele—in other words, the complaints most frequently met with in general practice—have been treated with extreme thoroughness and judgement. Chapter xxv, on the vas deferens, spermatic cord, and epididymis, is especially good. One of the authors has previously published original experimental and clinical observations bearing on infections of the epididymis, and as a consequence the pages dealing with this condition have a special value. Contrary to the old teaching he has found that blood-borne infections of this structure are by no means infrequent. The initial site of such infections is in the tail of the epididymis, and is interstitial or peritubular rather than within the lumen of the canal. The authors are of the opinion that in tuberculosis, as well as in non-tuberculous infections of the epididymis, the path of invasion is through the blood stream. In only a few cases do they consider that primary infection lies in the prostate and vesicles. Chapter xxviii, on sexual impotency and sex neuroses, has been contributed by Dr. Irvin S. Koll. If this is to be criticized it is on the score that cases of impotency, in which an organic lesion is discoverable, have been given too large a place and the far commoner condition of psychological impotency scamped. It is this latter type of case that presents such great difficulty to the general practitioner, and we would have liked to see more space allotted to it. The treatment of these patients falls, however, within the province of the psychologist rather than of the genito-urinary expert, and it may be for this reason that Dr. Koll has not gone more fully into the matter. After reading a work such as this, written expressly for the general practitioner and student, many thoughts come into one's mind. Can any practitioner of ordinary mental calibre and attainments be expected to acquire a quarter of the knowledge that is provided for him? Granted that all unnecessary details have been eliminated, enough still remains to stagger even the most courageous of readers. In our opinion Eisendrath and Rolnick's work will be mainly valuable as a work of reference to which practitioners and students may turn. It will also be of service to those general surgeons who wish to revise their knowledge of urology as quickly as possible. In its printing considerable use has been made of heavier type to emphasize statements that the authors consider of primary importance. It is therefore possible to glean the main features of any disease and the salient points in its treatment with a minimum of reading. The fact that such a method of writing must of necessity entail a dogmatic attitude is an advantage rather than a disadvantage. It is unnecessary for the average student or practitioner to know that views opposite to those held by the authors may be in existence. A precise and emphatic mode of exposition is essential in such a work. Full advantage has been taken of illustrations, diagnostic tables, and diagrams as a means of presenting the subject in as brief and comprehensible a form as possible.

HAEMATOLOGY.

Elementary Haematology,[1] by Dr. W. E. COOKE of Wigan, is a concise handbook for students and practitioners on the methods of examining the blood and on the principal diseases of the blood-forming organs. After a useful account of the technique, the embryology and pedigree of the circulating cells in the blood, the normal and pathological forms of the red and the white blood cells are described. To supplement the text, photomicrographs, successful so far as they can be, are introduced, the author explaining that coloured drawings have not been used because it is the first essential that students should recognize structure rather than colours. This, however, is hardly a convincing argument, as stains are necessary, and great help can undoubtedly be given by exact representation of the appearances thus produced. In the chapter on the polynuclear count the Arneth count is described, and the five classes of the polymorphonuclear leucocyte are figured. The value of the Arneth procedure in ascertaining the presence and the severity of an infection is acknowledged, and an indication is given of the assistance it may afford the physician in making a prognosis. Dr. Cooke then summarizes the various forms of anaemia in a thoroughly up-to-date manner from the etiological, clinical, haematological, and therapeutic points of view. Accounts of splenic anaemia, acholuric jaundice, the leukaemias, purpura, Hodgkin's disease, and Gaucher's splenomegaly are on similar lines. Under the heading of splenic anaemia the term "Banti's disease" appears as a synonym, whereas it would be better to reserve the eponymic title for the later stage in which cirrhosis of the liver has supervened. Brief mention is made of "Hodgkin's cirrhosis" of the liver—presumably lymphadenoma with fibrosis of that organ is meant, but this being an unfamiliar phrase deserves some such explanation. Erythraemia and erythro-leukaemia (or the combination of erythraemia and myeloid leukaemia—a pan-myelosis), are also succinctly described. The clearness and brevity of this handbook should make it a useful companion to the student working in the wards, who will probably forgive the absence of references to authorities.

In his monograph on the clinical significance of qualitative changes in white blood corpuscles[2] Dr. WALTHER GLOOR attempts to correlate the changes observed in the nucleus and protoplasm of the polymorphonuclear leucocytes with the severity of infection as reflected by clinical evidence. He contrasts the morphology and staining reactions of the protoplasm, granules, and nuclei of the white blood corpuscles in healthy and in diseased conditions, and finds that the ageing of the nuclei, as determined by the fine reticular structure and the degree of pyknosis, does not necessarily go with the amount of nuclear segmentation. Dr. Gloor regards the five classes of polymorphonuclear leucocytes of Arneth as unnecessary, and gives preference to the method known as "Schilling's haemogram"; but for practical purposes he considers that both these schemes are unreliable and of doubtful diagnostic or prognostic value. He suggests, in agreement with Naegeli, that some of the cells with unsegmented nuclei are not young cells from stimulated bone marrow, but injured forms of mature cells derived from the site of infection. From the results of his clinical and experimental observations Dr. Gloor concludes that the qualitative changes in the leucocytes resulting from an infective process are referable partly to reaction of the bone marrow and partly to activity of the white corpuscles themselves at the site of infection. When the infection is by toxic action, and local inflammation is in abeyance, there is more nuclear and less protoplasmic change; there is stimulation of the bone marrow, and a shift to the left of the nuclear classes. But toxic protoplasmic changes, with the production of "toxic granules," result from a local inflammatory focus. The early and late stages of lobar pneumonia are illustrations of local and general toxic infection. The book is accompanied with twenty-nine figures in the text and four coloured plates. There is also a good bibliography.

PATHOLOGY OF THE NERVOUS SYSTEM.

WITH the publication by Masson of the twenty-first volume of their *Nouveau Traité de Médecine*,[3] edited by MM. ROGER, WIDAL, and TEISSIER, there has appeared the third of their four volumes devoted to a description of the pathology of the nervous system. This well maintains the high standard set by the two former volumes, and should find a place in every medical library as an authoritative work of reference. Dealing as it does with the peripheral nerves, the sympathetic nervous system, and the neuroses, it has a very wide field to cover, and requires all of its nine hundred large pages to deal adequately with this material.

The affections of the peripheral nerves, including the roots and trunk, are all described by Dr. Tinel in chapters which are unsurpassed in wealth of detail and profuseness of illustration. This section of his work is admirable in every way, and no exception can be taken to his method of treatment. It is a pity that affections of the trigeminal and facial nerves have been reserved for another volume dealing with the cranial nerves as a whole, for it would have been a great advantage to have had here included Dr. Tinel's views upon tic-douloureux and facial palsy, both of which still require much elucidation as far as the ordinary phenomena of their occurrence are concerned, and stand in marked contrast to lesions of other peripheral nerves. None of the other sections of the book enjoy the same unity of authorship, and all fall below its standard. They deal with difficult material of which much more is known clinically than has been established pathologically, and few clearly cut syndromes can be established. Epilepsy as a symptom always secondary to some essential disturbance is treated in a very thorough manner, with full attention to recent work and views on etiology, site of origin, nature of the phenomena, etc., and the chapter on the migraines is almost as exhaustive. In the final chapter Dr. Crouzon has collected together many genealogical records of patients with diseases of the nervous system which appear to have some familial and hereditary incidence. His discussion of these and their bearing upon Mendelian doctrine is of extreme interest.

There is a tendency throughout this volume to discuss the diverse views of the authorities quoted without sufficient critical evaluation of their work and its claim for consideration. This arises, no doubt, from the authors' desire to be as comprehensive and impartial as possible. Further, from its essentially anatomico-physiological point of view the book lacks the living interest which is always inspired by a clinical approach to the phenomena and syndromes of disease. It is, nevertheless, a work which commands respect, and takes unchallenged place as a standard treatise in this field.

SURGERY OF BRAIN TUMOURS.

DR. OLIVECRONA, in his *Surgical Treatment of Tumours of the Brain*,[4] gives a detailed record of 85 cases of cerebral tumour operated on by him. The general results as regards those tumours, the nature of which was verified, were as follows. Of 28 supratentorial gliomata about one-half died from the operation, one-fourth within a few months, and one-fourth showed improvement; in 8 of the cases a partial or total excision was possible, with complete relief of symptoms after from three months to one and a half years from the operation; simple decompression showed much less favourable results, all the patients, except one, dying within nine months. Of the patients with subtentorial gliomata, 5 died as the result of the operation, and 4 lived for one to two years with relief from symptoms. Of 7 patients upon whom complete excision of meningiomas was performed, 4 died as the result of the operation,

[3] *Nouveau Traité de Médecine.* Publié sous la direction de MM. C. H. Roger, Fernand Widal, P. J. Teissier. Fascicule XXI: Système Sympathique, Névroses. Paris: Masson et Cie. (Roy. 8vo, pp. viii + 900; illustrated. 35 fr. sans majoration.)

[4] *Die Chirurgische Behandlung der Gehirntumoren.* Von Dr. Herbert Olivecrona. Unter mitwirkung von Dr. E. Leysholm. Berlin: J. Springer. (Sup. roy. 8vo, pp. iv + 344; 228 figures. R.M.27.)

while 3 were practically cured. Of eighth-nerve growths, 9 enucleations were followed by 2 deaths from the operation, with cure or improvement in 7 cases; one decompression ended fatally, as did one case of cyst drainage and one of partial excision of bilateral growths. Of 2 congenital cystic tumours of the infundibulum, one partial excision ended fatally, while one complete excision showed freedom from symptoms six months after operation. A very large cholesteatoma of the lateral ventrical was completely cured by extirpation. An excision of a tuberculoma ended in death from tuberculous meningitis within two months, and an attempt to extirpate a large angioma of the vermis was relinquished on account of haemorrhage, the patient dying on the day following a second operation.

INFANT FEEDING.

AFTER the production of many volumes by specialists on the feeding of infants it is interesting to read the views and experience of a general practitioner, and for this reason Dr. HOWARD B. GLADSTONE's book *Clinical Observations on Infant Feeding and Nutrition*[7] is welcome. The author states in his preface that he has not had so much time as he would have liked in which to analyse the clinical material that came under his notice, and this may perhaps account for such generalizations as that healthily breast-fed children may "often put on a pound a week and are all the better for it," and also for a certain lack of clearness here and there in the presentation of opinions and procedure. On page 17 there is a heading "Methods of humanizing the milk," but no details are given until a later chapter (p. 32). Certain methods of diluting milk are set out and labelled Diet 1, 2, 3, 4, etc., and attached to each is the statement that the caloric value is, for example, "200," but whether this is per ounce or per feed or per day is not stated. In regard to pyloric stenosis, we note that Dr. Gladstone recommends medical treatment up to a point, with the injunction that a surgeon should be called in if these measures fail; this is not in accordance with modern teaching. Speaking generally, his results in the treatment of ailing babies appear to be remarkably good. Thus from his record of a bad epidemic of infective colitis with which he had to deal, we learn that he treated 103 cases in the homes of the poor with only three deaths.

NOTES ON BOOKS.

IN the second edition of *The Science and Practice of Surgery*,[8] by Mr. W. H. C. ROMANIS and Mr. PHILIP H. MITCHINER, which follows swiftly upon the first edition, reviewed in our columns of November 5th, 1927 (p. 831), the whole work has been revised, notably the chapter concerning injuries of the extremities, and a number of new subjects, among them the injection treatment of varicose veins, periarterial sympathectomy, perimetry, and the radium treatment of malignant disease, have been dealt with. A few new figures have been introduced, and many of the *x*-ray photographs have been replaced by others clearer in outline. A useful innovation has been the inclusion at the end of each volume of an index to the whole work. This second edition, with its new features and improvements, should be assured of an even greater success than the first.

In the preface to the ninth edition of his vade-mecum of special surgery and orthopaedics[9] Dr. ZIEGNER states that almost every chapter has been added to and remodelled, and that here and there he has brought to mind much out of general and border surgery. The book is arranged on a regional basis, each part of the human organism, with its injuries, its diseases, and surgery appropriate to them, being taken into consideration in turn and very briefly discussed. As there are no illustrations no attempt is made to teach the reader diagnosis or methods of treatment, for which he must go to the far more valuable method of clinical experience and larger manuals and textbooks. The practitioner, however, who finds himself confronted with a problem in diagnosis and surgical treatment will find in this book something to help him, if not complete instruction and guidance. The English-speaking reader must not be misled by the title of *Speziellen Chirurgie* into thinking that this book deals with what we call specialties in this country. It may be useful as a kind of index to surgical treatment, full information on which must be sought elsewhere.

Sulphur therapy[10] is a small volume in which various authors deal with different aspects of the subject. Dr. T. GORDONOFF gives an account of the pharmacology of sulphur. He refers to some interesting researches of his own in which he showed that administration of sulphur caused a reduction in the blood sugar and an increase in the liver glycogen in animals. He suggests that there may be some connexion between this fact and Abel's conclusion that insulin was a labile sulphur compound. Professor R. MEYER-BISCH deals with sulphur therapy in general, and discusses the use of sulphur baths and sulphur administration in the treatment of chronic arthritis and hyperpiesis. Dr. PAUL UNNA, jun., discusses the use of sulphur in skin diseases.

Dr. EVEREST's work on *The Higher Coal-tar Hydrocarbons*[11] is a useful addition to the literature of the subject. Substances wholly composed of carbon and hydrogen occupy a field of chemistry all to themselves. Those which are found in coal tar, or may be produced from it, have the peculiar interest that they are the head members of important groups of fine chemicals. These hydrocarbons have received, on the whole, more scanty attention than was their due; research has been less prolific among them than perhaps in any group of equal importance. Everest has collected the scattered literature and presented the facts in a readily accessible form. The treatise deals not only with the characters and properties of the hydrocarbons themselves, but also with the important products they yield. The chief features of these are described, and also the reactions by which related products are obtained from them. References to original publications are incorporated, within brackets, in the body of the text; these helpfully simplify the work of the inquirer. The book will prove valuable as well to those engaged in industrial research as to the academic worker.

No comprehensive book on human microscopical anatomy has appeared since the last edition of Koelliker's treatise, and as great and numerous advances in knowledge have been made since that time, Professor v. MÖLLENDORFF has undertaken the task of editing a work which shall embody our present knowledge in every detail. It is proposed to complete the work in eight volumes, the first two dealing with the tissues and the remainder with the microscopical anatomy of the organs. The first part of volume five[12] deals with the anatomy of the mouth, the salivary glands and pancreas, the tonsils, pharynx, oesophagus, and peritoneum. An examination of this volume, which is written by Professors Hellman, Schumacher, Seifert, and Zimmermann, shows that the work is not merely descriptive, but that the biological aspect has been kept in view, the developmental and physiological features of the subject being duly considered, while the facts of comparative anatomy and pathology are made use of wherever they serve to throw light on details of the normal human anatomy. The most striking feature of the volume is, perhaps, the great increase in the facts relating to cytology.

The production of books of the type of *Aids to Biochemistry*[13] is probably due to the array of examinations which have to be passed by the medical student; and the examination system is certainly the chief justification for their existence. The subject-matter of biochemistry does not lend itself to the tabulation, cross-heading, and compression necessarily adopted in the "Aids" series: furthermore, its relationship to other branches of physiology and medicine needs due consideration. For a student who has completed a course of biochemistry, and who wishes merely to refresh his memory on certain technical points of a more or less practical nature, the volume before us has many advantages. It is clear, concise, and contains a

[13] *Aids to Biochemistry.* By E. Ashley Cooper, D.Sc.Lond., F.I.C., and S. D. Nicholas, B.A.Oxon., A.I.C. London: Baillière, Tindall and Cox. (Fcap. 8vo, pp. viii + 163; 12 figures. 4s. 6d. net.)

remarkably large amount of information in an accessible form. It would, however, be disastrous if the low price and compactness of such publications should tempt the student to regard them as in any way fit substitutes for lecture notes or text-books.

A book on *Volumetric Glassware*[14] has been prepared by VERNEY STOTT of the National Physical Laboratory. This describes methods of standardization and discusses the errors incidental to volumetric operations. It is a work of particular value to manufacturers of glass apparatus, not only for the sake of the information it gives, but for its authoritative origin.

The A B C of Vitamins,[15] by Mr. JOHN PRYDE, M.Sc., contains an up-to-date and entertaining account of our knowledge of vitamins, and of the methods by which this knowledge has been gained. As may be expected of a book by a biochemist of Mr. Pryde's standing, the information is, on the whole, accurate, though the validity of one or two statements may be questioned. For example, has the pleasant hypothesis that the cod obtains its vitamin D from the plankton ever been verified? Experimental work carried out before the establishment of the distinction between vitamins A and D cannot be said to afford satisfactory evidence. The statement on page 34 that vitamin D usually occurs along with vitamin A is ambiguous. It is true that "D" is usually accompanied by "A," but "A" may appear, as in green leaves, without the accompaniment of "D."

The eleventh edition of *From Cloud to Sunshine*[16] follows close upon the heels of its predecessor. It is a succinct and prettily illustrated guide to the beauties of Algiers and Algeria, and there is a chapter on the medical aspects and applications of its climate, which, even in mid-winter, is mild and sunshiny. Although as much rain falls, possibly, as in Paris or London, it comes down so heavily that the number of rainy days is comparatively small; moreover, two-thirds of it falls at night—a delightful arrangement which one would like to see introduced over here.

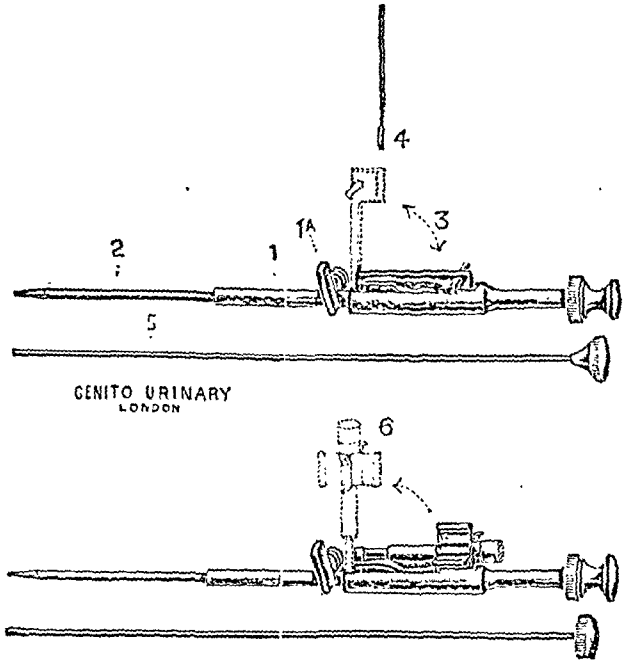
PREPARATIONS AND APPLIANCES.

RADON SEED INTRODUCER.

MR. DUNCAN C. L. FITZWILLIAMS, M.Ch., F.R.C.S., writes: The radon seed introducer here illustrated was shown at the International Cancer Conference held in London last summer.



The barrel of this instrument consists of two tubes. The outer tube, marked 1, slides up and down and can be fixed by the thumbscrew 1A. This allows the operator to set the instrument at the exact depth at which it is desired to place the first seed, and all subsequent seeds can then be placed at an equal depth; moreover, second and third time seeds can be placed at different levels. The inner tube, marked 2, is the cannula; through this cannula the trocar is fixed to transfix the tissues. At the butt end of the instrument is a breech, shown closed, into which a magazine in dotted outline, marked 3, fits.

In using the instrument the breech is opened and the magazine (3) is loaded with a seed (4). The depth at which the seed is placed is determined by sliding the outer tube (1) and fixing it by the screw (1A). The instrument is plunged into the tissue till the shoulder of the outer tube stops it. The trocar is withdrawn, the magazine snapped into the breech, and the introducer (5) pushes the seed into place; the introducer is removed, and the magazine is raised and loaded again. The instrument can be inserted again by replacing the trocar, or it can be partly withdrawn and moved in another direction.

For multiple seeds a magazine (6) to hold four can be fitted; this revolves like the magazine of a revolver, so that four seeds can be inserted in different places, all at the same distances from the point of insertion.

It is of value to dip the seeds into antiseptic vaseline before loading the magazine.

The instrument is placed on the market by the Genito-Urinary Manufacturing Company, 28A, Devonshire Street, W.1.

ADVERTISEMENTS OF ABORTIFACIENTS.

A CIRCULAR in the following terms was issued by the Advertising Association (Inc.) to every newspaper in this country, and it has been suggested to the British Medical Association that its publication in these columns would be welcomed by the medical profession.

The Advertising Association has given careful and serious consideration to the advertisement and sale of alleged remedies for complaints peculiar to women which have appeared in certain publications. It cannot be too widely known, or too clearly emphasized, that these advertisements are, in a double sense, a source of grave danger and abuse. In the great majority of cases "irregularity" in a woman is a symptom of pregnancy; in the other cases it is probably a symptom at least of a condition requiring skilled medical treatment, and sometimes of serious disease.

It is desired to make it perfectly clear that the Advertising Association is not concerning itself with the sale or use of contraceptives, nor, indeed, with any question of morals involved in such sale or use. But the procuring of abortion is a serious crime, punishable by a long term of imprisonment for all parties concerned.

The association has consulted the Director of Public Prosecutions in regard to this matter, and he has expressed the firm opinion that these advertisements are a serious source of danger to those whom they reach, and states that they are the object of the close attention of his department. A case was recently heard at the Central Criminal Court before the Recorder of London where the parties charged sold remedies for "irregularities" through the medium of advertisements inserted in certain newspapers. These persons were convicted and sentenced to imprisonment, the Recorder commenting in severe terms upon what he called "this pernicious traffic."

It cannot be too strongly urged that all advertised "remedies" for female ailments are capable of harmful results if taken in large quantities, and the advertising of them is open to such grave abuse that a strong case can be made for the refusal of such advertisements by all journals jealous of their reputation. Even where these advertisements contain, as is frequently the case, warnings that the "remedies" are not to be used by pregnant women, they are equally mischievous, as such warnings amount to inducements in many cases to acquire the "remedies" for abortion purposes.

The evidence given before the Parliamentary Select Committee on Patent Medicines went to show that, in the majority of cases, these advertised remedies are purchased definitely and deliberately where pregnancy is admitted or suspected, in the belief that they will bring about the termination of that condition. The drugs advertised may or may not be efficacious in bringing about the desired result, but there can be no doubt as to the purpose for which they are, in the majority of cases, purchased.

This association, therefore, after deliberate consideration and consultation with those competent to express authoritative medical and legal opinions, has decided, while recognizing that many papers already exclude such advertising, to appeal to the press of the whole country, to advertising agents, and to others concerned, to decline to accept any advertisements of drugs or treatment purporting to be remedies for disorders generally termed irregularities, female ailments, or women's complaints. Such action would undoubtedly win general approval from the great mass of newspaper readers, and would, in the opinion of the Advertising Association, constitute a public service of great value to the community.

British Medical Journal.

SATURDAY, FEBRUARY 23RD, 1929.

CHRONIC RHEUMATIC DISEASES.

THE subject of chronic rheumatism is engaging more and more interest at the present time. Sir George Newman, in his annual report, has again insisted on the importance of the group of rheumatic diseases as a cause of industrial disablement, and the representative character of the conference held under his presidency at Bath last May directed public attention to the urgency of the problem which has to be dealt with. One of the main conclusions which emerged from the meeting was that no single theory could account for the genesis of rheumatic disorders, nor could any one form of treatment bring about their cure. The day has passed when all symptoms can be put down to infection, to metabolic defects, or to any other single factor; indeed, so complex are felt to be the problems presented by diagnosis and treatment that in the United States of America, as well as in many European countries, committees on rheumatism have been set up, and many of these bodies are directly recognized and subsidized by Government departments. In Great Britain there is a marked increase in the amount of research work and scientific clinical investigation at the spas, where at present the material for investigation is found in greatest concentration. Under the aegis of the Red Cross Society, London is establishing a special clinic for rheumatism, and this forward movement may shortly be followed in other large centres. Friendly societies are striving to find the means to extend spa benefit to their insured patients, and the demand for beds in the special rheumatic hospitals is probably greater to-day than it has ever been.

The Ministry of Health has issued a special report on chronic rheumatism by Dr. Alison Glover, and there have been many contributions to the literature of its pathogenesis and treatment. In our present issue (p. 338) Dr. F. D. Howitt calls attention to the theory advocated by Pemberton and others that the various forms of chronic rheumatic diseases are allergic reactions in specially sensitive persons to a variety of infections, and refers to the importance in treatment of elimination, especially by the skin, and to the applications of heat to that end. Heat may also act, however, by inducing redistribution of circulation and relieving local capillary spasms in the muscles and the skin. Thus Schulhof, reviving Quincke's theory, suggests that rheumatic diseases are due to capillary stasis in frigisensitive subjects, a contention which, like others, probably represents one facet of the total presentation, but by no means the whole. It would seem that so far as these diseases are concerned we must adopt a three-dimensional point of view. We have to explain why apparently the same sort of conditions produce different effects in different patients; why the conditions held to be responsible for rheumatic diseases may obtain in many subjects without in fact producing any symptoms of such diseases; and why individuals suffering from apparently closely similar symptom-complexes do not respond in equal measure to the same form of treatment. To achieve such an exposition we must in the first place consider the effects of heredity and bodily constitution; we must go back to the diathesis of our fathers, but not stay there. Endocrine dysfunctions, metabolic disturbances, special sensitivities, and the like, are all of importance, but are not the whole story. We must also consider toxic conditions, but not limit our vision to bacterial toxins only. We must be prepared to consider all varieties of general and focal infections, but we must realize that when such infections cannot be found it may be that they are not there. Further, we must be prepared to find that even when infections are discovered and removed the trouble may persist, simply because these sources of toxaemia were not those causing the symptoms. The responsible toxaemia may be chemical in origin rather than bacterial, or it may be derived from endogenous sources, such as the products of the patient's own metabolism or muscular activity. To all such poisons, as Dr. Howitt points out, the patient may be allergic. Lastly, we have to consider the factor of faulty elimination by any or all of the usual excretory channels of the body. In more than one recent article in the *British Medical Journal* attention has been drawn to the importance of the skin in this respect. Disordered sweat secretion may almost be said to be the specific characteristic of the rheumatic subject, and spa treatment, which has stood the test of more than 2,000 years, acts chiefly by improving elimination through the skin. It must not be forgotten, moreover, that the faults of elimination may be local as well as general, and if a joint or muscle is left overloaded with waste products rheumatic trouble is likely to develop and persist. Obviously, the relative preponderance of all these factors will vary from case to case. Every rheumatic patient must be considered, not only as an isolated individual, but in relation to his environment—climatic, emotional, and social. Special factors must also be taken into account in each of the varieties which these diseases exhibit.

In opening a discussion last week at the Balneological Section of the Royal Society of Medicine on the subject of osteo-arthritis, Dr. R. G. Gordon of Bath emphasized the importance of strain and lack of proper nourishment in the joint involved. He maintained that in the causation of osteo-arthritis infection probably played only a secondary part, while the condition itself might be a terminal stage of all the other forms of rheumatic disease. Dr. J. A. Thomson of Harrogate referred to the peculiarities of the *x*-ray findings in early cases of osteo-arthritis, and no doubt the elucidation of the causes of these and other peculiarities in the radiographic appearances in different types of joint disorders will help to solve the problems which the rheumatic diseases present.

The statistics of the incidence of rheumatic diseases and of the disablement they produce indicate clearly enough that no scheme for the control of rheumatism can be regarded as satisfactory unless it is planned on a large scale and affords facilities for the early diagnosis and treatment of every case. There is need for wide-spread recognition of three facts: that there is no longer any prospect of the discovery of a panacea for rheumatic disorders; that in our knowledge of their etiology and pathology there is still much chaos that has to be reduced to order; and, above all, that the greatest hope of their ultimate eradication lies within the province of preventive medicine. We may perhaps look to a time in the far distant future when faulty diathesis will be eradicated or compensated; when sources of toxaemia will never be allowed to establish themselves; when elimination has become adequate, and the individual adjusted to his environment or the environment to the individual. In such a golden age the reproach of rheumatism will have passed away, and with it a large part of palliative medicine.

THE LOCAL GOVERNMENT BILL.

THE Local Government Bill has now passed through all its stages in the House of Commons. The main principles on which it is based, whether regarded as a measure for the reform of local government administrative machinery or for the readjustment of rating, have suffered no alteration. There have been, however, a good many changes in important details, made with a view to correcting some manifest imperfections, or to conciliating bodies of critics who were, or thought themselves to be, adversely affected by the financial arrangements proposed. The general attitude of the British Medical Association to the bill, and the important points with which the profession is mainly concerned in connexion with its effect upon health administration, were set out in two recent leading articles in the *British Medical Journal*—one on November 10th (p. 854), and the other on December 1st last (p. 996).

Though the bill still remains a very important step towards that unification of health administration which the Association has made its aim for so long, the three main imperfections in this regard to which we drew attention are still unremoved. It was suggested that it should be mandatory upon, and not merely permissive for, the councils of counties and county boroughs to administer the functions transferred to them from the Poor Law authorities as far as possible by virtue of the appropriate Acts relating to public health services instead of through the Poor Law; and to co-opt on to the various committees concerned persons experienced in the work done by such committees, including representatives of the medical profession. It was further suggested that in the case of counties the council should be obliged, instead of being merely permitted, to delegate the exercise of transferred health functions to the councils of such county districts as had already established and efficiently conducted in their areas health services of a similar kind, thus avoiding an absurd overlapping or reduplication of work. These three matters—the distribution of functions, the delegation of functions, the co-optation on committees—still remain permissive only. Certain declarations relating thereto have, however, been made by, or on behalf of, the Minister of Health, and these are encouraging in so far as they indicate that he regards such distribution, delegation, and co-optation as the most advantageous methods of administration in most cases, and as those which, in the course of time, are likely to be generally adopted. Until this is brought about the unification and efficiency of health services, though advanced, will obviously be very imperfect, and we hope that the Minister, in the memorandum which he must necessarily address to local authorities on the passage of the Act, may be able to indicate that he will regard it as desirable that these features should be incorporated in schemes submitted for his approval by the councils of those authorities. In certain other respects of relatively minor importance the bill has been amended to meet points to which we drew attention. In particular the rights of transferred medical officers with regard to superannuation and otherwise have now been fully safeguarded.

There may still be some further amendment of the bill during its passage through the House of Lords, but it seems unlikely that its provisions will undergo any material modification. We are therefore close upon what we have called the "scheme stage" of the reform of local government and the Poor Law. The council of every county and county borough must, within six months after the commencement of the Act, submit a scheme of the administrative arrangements proposed to be made for discharging its transferred functions. On the submission of an administrative scheme a notice must be published that representations thereon may be made to the Minister within a period of four weeks. Schemes sanctioned by the Minister will become operative on April 1st, 1930. There is thus still time for the medical profession, collectively or locally, to advise or press the Ministry of Health, or the local authorities, or both, in order to secure its objects. It is obvious that in each locality such pressure can be exercised more effectually during the preparation of a scheme than after its completion, and it is scarcely too early, even now, for the profession in the area of each county or county borough to inquire what is being done, and to try to induce the local council to embody in its scheme the features indicated above, and such others as will lead to the most effective local health administration. Particular regard may well be paid to the way in which it is proposed to administer and manage hospitals and Poor Law institutions under the scheme. Later it may be necessary to press the Minister not to sanction schemes which appear to be unsatisfactory.

It is desirable to note that, beyond the submission of these administrative schemes, there are no fewer than three very important surveys which the bill imposes upon the councils of counties, as distinguished from those of county boroughs. One of these, which must be completed by April, 1932, at the latest, is to review the whole area of the county as regards its division into districts and parishes, and to report any changes in this respect which it thinks desirable. A second is to survey the hospital accommodation for the treatment of infectious disease provided within the county, and to submit a scheme for making such provision adequate for every part of the area. A third survey is with a view to formulating arrangements for securing a whole-time medical officer of health, not necessarily at once, for every district of the county. It is clear that, as with regard to administrative schemes, so with regard to these surveys, which may exercise great effect upon health services and administration, the medical profession should exercise its due influence, and should at once prepare itself to bring such influence to bear at the appropriate time.

HOSPITAL SERVICES IN NEW ZEALAND.

THE appendix to the annual report of the New Zealand Department of Health dealing with hospitals and charitable aid for the year ended March 31st, 1928, contains much of interest to those concerned with hospital organization and administration in this country. A comprehensive account of the New Zealand hospital system, based upon the appendix to the Health Department's report for the previous year, appeared in the *British Medical Journal* of July 14th last (p. 57). We may recall that the hospitals of New Zealand are maintained by local hospital boards financed mainly by public funds; in the year 1927-28 levies on local authorities amounted to 33.5 per cent. of the revenue, Government contributions to 41.6 per cent., recoveries from patients to 20.5 per cent., voluntary contributions to 1.7 per cent., and income from other sources to 2.7 per cent. The burden on public funds, it may be added, has risen from £505,852 (8s. 10d. per head of population) in 1916-17 to an estimated total of £1,544,753 (21s. 3d. per head) in 1928-29 for hospitals and charitable aid. Commenting on the rise in expenditure, the report observes that its reasonableness may only be judged in relation to whether the benefits received are proportionate

to the increased cost. "The people . . . have demanded and obtained a sufficient and, on the whole, efficient hospital service, and an increasing proportion of the population are using the hospitals. So long, therefore, as those receiving treatment pay as much as they can reasonably be expected to pay, and the relief is administered in an economical manner, the increased cost to public funds is not a sign of waste or extravagance." The situation is contrasted with that prevailing in countries where the voluntary system exists, and it is suggested that a permanent state of affairs in which sufferers should be unable to obtain admission to hospitals owing to the financial difficulties of such institutions "seems somewhat incompatible with the advanced civilization of the twentieth century." In New Zealand, if a hospital is unable to accommodate its patients it may be instructed to increase its size, the cost being shared equally by the Government and the ratepayers. The system as it exists provides 5.5 beds per 1,000 of population; in England and Wales the voluntary hospitals provide less than 1.5 beds per 1,000 of population, and the Poor Law authorities provide under 1 bed per 1,000 of the population in institutions maintained exclusively for the sick (that is, separate infirmaries and sick asylums). It would be unwise to attach too much importance to these figures, for due regard must be given to the fact that sick persons are also received in "general mixed workhouses" and other institutions, while the New Zealand figure apparently relates to all forms of hospital accommodation; but the contrast is nevertheless striking. Account must, moreover, be taken of the fact that the provision of hospital facilities in scattered districts, as in such a country as New Zealand, implies the existence of a much higher proportionate surplus (or reserve) of accommodation than is necessary in the larger institutions found in closely populated areas. Although the system prevailing in the Dominion appears to provide a satisfactory service in many respects, it is by no means without its problems, and, from the "defensive" tone of the report, seems to have been faced with a good deal of criticism. It should be noted that the medical staff remain on an honorary basis, and that while the policy of the New Zealand members of the British Medical Association favours the continuance of such free service in public wards, provided that accommodation is made available for the private treatment of their own patients, the authorities generally are disposed to consider that the medical staff should be stipendiary. There are also divisions of opinion—acute in some cases—on many aspects of the methods of finance and control, and on the attitude of the friendly societies towards the hospitals. The question of giving special consideration to patients able and willing to make payments in excess of those now customary (that is, from 9s. to 12s. per day) is also attracting attention, and the recently issued report of the Pay Beds Committee of the King Edward's Hospital Fund for London is discussed at length. Apparently the wards of the public hospitals in New Zealand are being used increasingly by those well able to pay at least moderate fees for the services rendered, and it is urged that the time is coming when the provision of pay wards should be considered. The main obstacle to discussion of the question on its merits appears to be what the report describes as "the class-distinction bogy," arising from a belief that any division of patients on the basis of ability to pay must involve discriminating treatment. In answering this objection an ingenious comparison with the conditions of railway travel is drawn: "Class distinction is observed in that one can travel first or second class; but both classes arrive at their destination in the same degree of safety at precisely the same time, and both classes derive exactly the same benefit from the highly skilled engineers and operators, enabling them to fulfil their journey in equal safety."

A DESCENDANT OF JOHN HUNTER.

On February 11th there died in the Sisterhood Home, St. Hilda's, Shirland Road, Paddington, where she chose to spend the evening of a life spent in well-doing, Miss Helen Hunter-Baillie, the senior representative of the Hunter family and a woman of exceptional ability. She was 85 years of age, and could read without glasses and retained her freshness of mind to the end. On the death of her sole surviving brother in 1895 she became "laird" of Long Calderwood—the birthplace of William and John Hunter, and also of Dorothea Hunter, who became the mother of Dr. Matthew Baillie, physician, and Joanna Baillie, poetess. The excellent state of preservation of the old farmhouse at Long Calderwood is owing to Miss Hunter-Baillie's care and vigilance, and to the keen and intelligent interest she took in all that pertains to the men who did so much to mould the progress of medicine in this country during the eighteenth century. Her father, Mr. William Hunter-Baillie, was the only surviving son of Dr. Matthew Baillie, and was born in 1797 within the school which Dr. William Hunter built in Great Windmill Street—a building which still serves as an annexe for the Lyric Theatre. He was educated at Westminster School and Balliol College, Oxford, was called to the Bar, and, although he never practised, did act for a time as marshal to his distinguished uncle Lord Denman. He inherited a fortune from his father, devoted himself to literature, society, and good works, and imparted much of his tastes and learning to his daughter, Miss Helen Hunter-Baillie. He lived for the greater part of his life at 96, Harley Street, and died in 1894 at the age of 97, and in his home Miss Hunter-Baillie met the leaders of literature and science of the nineteenth century. She wrote in her retreat a small typewritten volume of valuable reminiscences, a copy of which is preserved in the library of the Royal College of Surgeons of England. From it we learn that "she came out just as crinolines were coming in," and that she "thought the fashion charming." Her home atmosphere was strongly evangelical, but she and her sisters became ardent participators in the Anglo-Catholic movement. She gave herself to social service within the Church, and, if private circumstances had permitted, would have given herself to the order of sisterhood. As it was she became an associate of the order, and laboured in lay missions for forty-six years, first in the East End of London, then at Lisson Grove. From her father she inherited a strong sense of justice—justice, or equality of opportunity, for women—but the means she advocated and pursued were those of reasonableness and patience. Her interests were many and wide, and, fortunately for students of medical history, she had a keen and true sense of what constitutes a "record." At an early date she began to collect all old letters which had come down in the family from the Hunters, Baillies, Jenners, Barons, Denmans, Crofts; and these she arranged and catalogued and bound in seven volumes, and presented this valuable collection of documents to the library of the Royal College of Surgeons. To Miss Hunter-Baillie and to her brother, Captain William Hunter-Baillie, the Royal Colleges are indebted for many valuable portraits and busts of the Hunters, Baillies, and also of Jenner. At the Hunterian Oration, given biennially in the theatre of the Royal College of Surgeons, she was always a welcome guest, and had assigned to her a place of honour, which she well became. Students of the lineaments of John Hunter saw in her face, head, body, deportment, and inquiring mind much which reminded them of those of her grand-uncle. She was keenly interested in the Hunterian Collections preserved in the museum and library of the College. Miss Hunter-Baillie is now represented by the children of her two younger sisters—Henrietta, who married the Rev. J. Maconochy of All

Saints', Norfolk Square, and Agnes, who married the Rev. R. B. Oliver of Whitwell, Isle of Wight. In the Oliver family she had two nephews—the Rev. B. L. Baillie Oliver and the late Matthew William Baillie Oliver, F.R.C.S., whose early death three years ago was a great blow to her. These two nephews have left no descendants. A daughter of Mrs. Maconochy became the wife of Dr. T. Battersby Jobson; of that marriage there are four children. Thus, of the ten children born to John Hunter and his wife Agnes Paul, in the farmhouse of Long Calderwood two centuries ago, there are now only eleven lineal living descendants, representing the fifth and sixth generations. Although these are all that are descended from the Calderwood branch of Hunters, there is another line of Hunters which traces its origin to a senior brother of the John Hunter who became laird of Long Calderwood. The representative of this senior branch is Colonel C. S. Hunter, D.S.O.

NO. 3 CANADIAN GENERAL HOSPITAL.

On the occasion of some Armistice Day celebrations, when flamboyant banners, and inscriptions in keeping, were in strong evidence, a Canadian contingent paraded under a tiny standard bearing in small letters the modest legend, "We were there too." That the Canadians "were there too" the British people are not likely to forget, and not the least of the reasons for their gratitude is the prompt provision of the famous medical unit whose history has now been told by R. C. Fetherstonhaugh.[1] Shortly after the outbreak of war the dean of the Faculty of Medicine of McGill University, Lieut.-Colonel H. S. Birkett, conceived the happy idea that McGill University should offer to the British Army a completely equipped hospital of 520 beds, the officers chosen from the staff of the faculty, other ranks to consist mainly of students, and the sisters selected from the large Montreal hospitals. The scheme was received enthusiastically, and as the head of each department of the proposed hospital Colonel Birkett secured a man outstanding in the professional life of Montreal and Canada. Needless to say, the university's patriotic offer was gratefully accepted, and to McGill belongs the proud distinction of being the first university in the Empire to furnish a medical unit for service overseas. While the hospital was in process of organization Canadian headquarters telephoned asking if the university could double the capacity of its unit, in view of the decision that all general hospitals were to contain 1,040 beds. Without leaving the telephone Colonel Birkett replied that McGill's offer of a general hospital still held good. The history of the hospital—which operated first in Dannes-Camiers and then in Boulogne—is based on official war diaries and similar records, and this accounts for a certain abruptness of style unavoidable in a compilation made up from such sources. The hospital work and events of the daily round are recounted in great detail, with interesting professional notes, and here and there abstracts of reports on special subjects rendered by the staff. If any reader feels that some of the details of ordinary happenings have little general interest, let him think of the future and reflect how highly we to-day should value a similar account of the daily routine in a hospital of, say, the Seven Years' war. The subject-matter of the book does not lend itself to condensation, being itself based on summaries of events, but the fact that from first to last the admissions numbered 143,762, and 11,395 surgical operations were performed by the staff, gives an idea of the magnitude of the work accomplished. One of the staff, Lieut.-Colonel John McCrae, whose untimely death is still deplored, won fame wider and more lasting, perhaps, than any other in the war, except for a few leaders of the first rank. One morning, after the second battle of Ypres, he gave a colleague a torn piece of wrapping paper on which he had pencilled the moving and now famous lines beginning, "In Flanders fields the poppies blow"; and so, like Charles Wolfe, McCrae put on immortality through the medium of a single poem. The volume is well illustrated with photographs, and in appendixes are recorded the names of all who served in this honourable company.

PRACTICE AND FATIGUE.

In one of the Monograph Supplements of the *British Journal of Psychology*[1] Mr. J. C. Flügel describes in detail the results of an arithmetic test applied to forty-six elementary school children. The subjects were girls, aged 9½ to 13½, and every day for a period of ten weeks (except on Saturdays and a few extra holidays) they performed the test for a period of twenty minutes at the end of their ordinary morning's work. They used Kraepelin's adding sheets, according to which the subject works down series of columns of single-place numbers, adding each number to the number immediately preceding it. In order to encourage the children to do their best, they were given a small regular payment and a bonus on each day that they beat their previous best record. These bonuses were larger and larger in successive weeks, so the incentive was an increasing one. Each subject kept a graph of her own results from day to day, and thereby realized her progress. The most striking result obtained related to the effects of practice. The total score on the last day of the experiment was three and a quarter times as great as that on the first day, and the rate of improvement apparently showed no sign whatever of falling off. It was, in fact, nearly steady from the fourth day onwards right to the end. This result appears at first sight to differ from that observed by other investigators with various mental and manual tests, as they almost invariably found that the rate of improvement gradually diminished, and tended to cease after a time. Probably the discrepancy is due chiefly to the tremendous improvement shown by the children, which the author's method of plotting does nothing to allow for. On an average, the number of additions made by the whole group of children increased at the rate of about a thousand a day, but whereas the total number of additions came to 73,000 on the last (or forty-sixth) working day of the experiment, it was only 30,000 on the fourth day—that is, the *percentage* rate of improvement was nearly two and a half times greater during the fourth and immediately succeeding days than at the end of the experiment. In order to be able to investigate the onset of fatigue during the course of the twenty minutes' session, the children were required to mark their results at five-second intervals, synchronous with the ringing of a bell, and to make a special mark every minute when the experimenter called out "Now." The average rate of work showed a *rapid fall* during the first minute, followed by a small and steady fall during the remaining nineteen minutes. The total fall from beginning to end was 14 per cent. on the additions made in the first minute, but it varied from the extremes of 3 to 38 per cent. in different children. The variations shown by individual children were very considerable, as might be expected. The speed of the quickest girl was nearly three times greater than that of the slowest girl, and during the course of the experiment the quicker girls improved (absolutely) at a more rapid rate than the slower ones; but their percentage improvement was rather less. In addition to being subjected to the test described, the girls were examined in respect of general intelligence and in arithmetical ability by Professor

[1] *Practice, Fatigue, and Oscillation.* By J. C. Flügel, B.A. The British *Journal of Psychology*, Monograph Supplements, XIII. London: Cambridge University Press. 1928. (Sup. roy. 8vo, pp. 82; 30 figures. 6s. (d. net)

Cyril Burt. In these qualities they showed a fair correlation with their speed of performing the experimental test, coefficients of 0.29 to 0.53 being obtained. The author endeavoured to determine whether the individual girls showed any natural rhythmical oscillations in their speed of working, but this portion of the investigation was rather disappointing, as the very distinct rhythm shown was evidently related to the one-minute signals given by the experimenter, and they eclipsed natural rhythms.

THE STORY OF LAURA BRIDGMAN.

BLINDNESS is a tragedy; deafness is almost as bad. To be both blind and deaf is a horror unthinkable to most of us. Yet there have been some mortals so afflicted who have overcome their disabilities when taken in hand by sympathetic and persistent physicians. The cases of Helen Keller and Laura Bridgman are well known. They represent early attempts at the education of defectives, which is nowadays part of the regular work of those who have the oversight of the numerous schools for the physically defective in all civilized countries. The tale of *Laura Bridgman*,[1] as recently retold by Mrs. Richards, gives some idea of the illimitable patience of Dr. S. G. Howe, founder of the Massachusetts School for the Blind in 1832. It is stated in this book: "When Dr. Howe first undertook the charge of the blind, he bandaged his eyes, and went thus about his father's house for many days, that he might guess a little of what it meant to be blind." There was the true experimenter. With such a spirit who can wonder that he was able to achieve marvels? Charles Dickens, when in the United States, paid a visit to Laura Bridgman, and he recorded in his *American Notes* his observations. "The thought occurred to me as I sat down in another room, before a girl blind, deaf, and dumb, destitute of smell, and nearly so of taste; before a fair young creature with every human faculty, and hope, and power of goodness and affection, inclosed within her delicate frame, and but one outward sense—the sense of touch. There she was before me; built up, as it were, in a marble cell. . . ." "From the mournful ruin of such bereavement there had slowly risen up this gentle, tender, guileless, grateful-hearted being." Laura Bridgman was a normal child until the age of 2 years, when she suffered from scarlet fever of a virulent type. Some two years later Asa Tenney—a singular old man regarded by some an eccentric, by some almost a "natural," and by Dr. Howe as a "sort of philosopher with a crack in his skull"—*took the child* in hand, and taught her by contact with woods and fields and streams, until she was aged 8, when she came under the care of Dr. Howe. The story is one that will put heart into the teachers of the physically defective.

THE OXFORD PRESERVATION TRUST.

"THE beauty of Oxford is a national possession, though the preservation of it is mainly a local concern." These words are taken from the second report of the Oxford Preservation Trust, which has been formed "to preserve for the benefit of the public the amenities of the City of Oxford and its surroundings, and for that purpose to acquire land in the vicinity of Oxford." The report opens with the statement that the Trust has had an exciting, busy, and fruitful year, and it is clear from the study of it that much has been done, and has been well done. The beauties of Oxford fall into two groups. In the first group are the lovely views of the city from the surrounding heights. No city, not even Moscow, can excel them. "Match me such marvel, save in Eastern clime." These are especially the delight of those who live in Oxford and learn to love its surroundings—the scholar gipsies of many centuries. Many of the famous sites need protection from modern developments. A former trust acquired the Hinckscy Heights; the present trust has expended its resources wisely and well by the purchase of a portion of Boar's Hill, one of the most beautiful of the viewpoints, and also by a purchase along the banks of the Cherwell near Marston Ferry. These sites are thus saved from the builder. But much still remains to be done. Wytham Woods and Headington Hill must be preserved, and large funds will be required for these and other purposes. In the second group are the buildings and streets of the city and university itself. A casual visitor, spending a few hours in Oxford, can see enough to be impressed by their beauty and to recognize certain incongruities. Two sites are at present exercising those managing the trust. The houses on the south side of Broad Street have to be rebuilt, and St. Aldgate's, between Christ Church and Folly Bridge, is in a period of transition. "The Broad" is the more prominent site, but St. Aldgate's has always been an eyesore to those entering Oxford from the south. Here the trust is on difficult ground; the purchase of streets being clearly impossible, it has to proceed by negotiation and advice. It is pleasant to note the spirit in which the trust has been met by the city authorities, the Oxford Town Planning Committee, the Oxford Chamber of Trade, and private owners of property. The view of Christ Church from Folly Bridge has now been opened up, but it is necessary to provide for permanent improvements. Certain serious blemishes remain in the city; thus, the road into Oxford from the east, the portion between the station and Carfax, needs to be transformed into a dignified and worthy entrance. Much has been done by tact, but it is clear that considerable funds are still required. It need not be feared that the trust is in the hands of cranks. Here and there the traditional spirit of Oxford may be recognized, as in the enthusiastic tone of the report, the accuracy of its grammar, the number of its commas, and the concluding statement of its objects, "to assist the development of rural community life," whatever this may mean. But over all is a spirit of sanity and good sense; the object of the trust is not to grudge new building, but to guide it. The Oxford Preservation Trust is indeed worthy of support; we should all agree with its aims and respond to its appeal: "Oxford does not want to live on doles from outside, but, while discharging its own part of the duty, feels that it may fairly ask all past and present members of the University, former citizens, and the multitude of those who enjoy the beauty and interest of the city, to help Oxford in preserving the unique and essential features of its charm."

INFLUENZA.

ALTHOUGH last week there was a considerable increase in the number of deaths attributed to influenza, the rate of increase slackened so much as to make it probable that the maximum will soon be reached. Unless the sudden onset of arctic conditions unfavourably affects the rate of mortality—which, since the present type of influenza has been least merciful to those advanced in life, is quite probable—we should expect the mortality of the next two weeks not greatly to surpass 1,200 in each, and that then there would be a decline. It appears that in the Liverpool area the influenza mortality is at or near its maximum. In Yorkshire only Leeds returned a large increase. In the south Portsmouth and Southampton seem to have passed their maxima. Only in London and the north-western area were there very large increases in the numbers of notifications of pneumonia. The course of the recrudescence will be followed with special interest, because this is the first time within the present post-1918 experience that so severe and widespread a period of intense cold has coincided with a considerable prevalence of influenza.

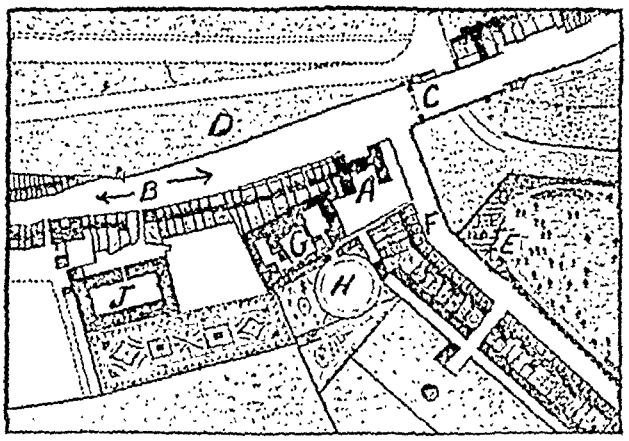
Nova et Vetera.

THE GROSVENOR PLACE SCHOOL.

THE private medical schools of London, which were flourishing at the beginning and in the first quarter of the nineteenth century, rendered great services to medical education. At a time when schools attached to the general hospitals were only in their infancy, these undertakings, which were conducted for the profit of their proprietors, gave the best education in medicine and surgery then obtainable in England. They deserved a better fate than befell them. Like the provincial medical schools, they were unable to face the competition of the rising hospital schools of the metropolis, which were favoured by the regulations of the College of Surgeons. The names of William Hunter, Joshua Brookes, Charles Bell, and Samuel Lane, all of whom conducted such undertakings, are household words in the history of British medicine in the late eighteenth and early nineteenth centuries. Among these Lane's name is closely associated with the rise of the medical school of St. George's and the foundation of that of St. Mary's Hospital. In a privately printed brochure[1] Mr. R. R. James, F.R.C.S., has lately given an account of the school conducted by Lane and others in Grosvenor Place, close to St. George's Hospital, together with a large amount of correspondence between Lane and his friends and some of the hospital staff, as well as other documents of importance. The school was established in 1830 by Lane in conjunction with Dr. J. A. Wilson, whose nickname of "Maxilla" represented not only his initials (J. A. W.) but his flow of language, taking over a number of students of the Windmill Street school from Mr. Herbert Mayo, who became lecturer at King's College. Lane's dwelling-house was at No. 1, Grosvenor Place, which is now the address of the Wellington Club, and he built a theatre and dissecting room at the back of it. A reference to Crutchley's map of London dated 1833 shows that although Belgrave Square was already built Grosvenor Crescent did not exist. To the south of the old hospital building, and covering the site of the present medical school and part of that of Grosvenor Crescent, was Tattersall's Yard and Ring, long known as "The Corner," a nickname since transferred to the hospital, and dear to all St. George's men. As Mr. James tells us, Tattersall, who was



A, St. George's Hospital. B, Knightsbridge. C, Hyde Park Turnpike. D, Hyde Park. E, Garden of Buckingham Palace. F, Grosvenor Place. G, Tattersall's Repository. H, The Ring at Tattersall's. J, Foot Guards' Barracks.

"stud groom to the Duke of Kingston, took a 99 years' lease of the site of the famous yard from the Grosvenor estate in 1766. This expiring in 1865, the site reverted to the Duke" (then Marquess) "of Westminster, who let it to St. George's Hospital on a peppercorn rent, so long as the site is used for charitable purposes, and on it were built the new block of wards of the hospital and the buildings of the medical school."

Obviously the site let to the hospital was smaller than that occupied by Tattersall, seeing that part of Grosvenor Crescent was cut out of it.

At the time of the foundation of Lane's school there was a narrow roadway leading into Tattersall's Yard, in which was the entrance to the school. In the accounts of the expenses of the school for 1842 is an item of thirty shillings for a board affixed to the north-east corner of Mr. Lane's house with the words: "To the School of Anatomy and Medicine ☞ 1st door on the left." Tattersall's ring and some of his buildings were also on the south side of this roadway.

The deplorable squabble which arose out of the contested election of an assistant surgeon to St. George's in 1834, at which Sir Benjamin Brodie's assistant, Mr. Cutler, was elected and Lane was rejected by the governors, was followed by years of bickering. The students of Lane's school got their clinical instruction in the wards of the hospital, which relied upon Lane and his colleagues for a supply of residents and dressers, but in 1836 another school was started in Kinnerton Street, Knightsbridge, which claimed to be specially that of St. George's Hospital. This was built on land owned by Sir Benjamin Brodie. Mr. Timothy Holmes, in his life of Brodie,[2] states that the money for the building and installation of the school was found by Brodie, who granted a lease at £276 a year. This school became a rival to Lane's, and at one time students from both met and worked together in the wards. Both schools seem to have suffered financially by this competition, and many attempts at amalgamation were made, but they all failed, until at last Lane was elected surgeon to the recently established St. Mary's Hospital, and his school became practically the anatomical school of that institution. After St. Mary's established a school of its own at Paddington (in 1854), the Grosvenor Place school still carried on under other teachers until 1863. Mr. James quotes from an article by the late Mr. Pickering Pick, which appeared in vol. 6 of the *St. George's Hospital Gazette*, as follows:

> "After Lane's departure the institution fell into very low water, and at the time of which I write there were very few students, although there were some very good teachers connected with it; Sir Spencer Wells, then Mr. Wells, lecturing on surgery, Dr. Lankester on medicine, Mr. Wm. Adams and Dr. Halford on anatomy, and Dr. Richardson on physiology, all well-known men in their day."

There seems no doubt but that Lane's chances at St. George's were spoilt by personal antagonism aroused by his eloquent and argumentative friend Dr. J. A. Wilson, physician to the hospital. Mr. Holmes and Mr. James both think, as we do, that he was badly treated. The loss was mostly St. George's, and St. Mary's gained by his secession. Lane died in his ninetieth year in 1892. His son, James R. Lane, who taught in his school, also became in due course surgeon to St. Mary's, and died in 1891. The extracts from the minute book of Lane's school which Mr. James quotes are chiefly of interest as showing how little profit accrued to the proprietor and lecturers of a private school of medicine in the forties and fifties of the last century. In 1840 the school had nine lecturers besides Lane himself, for whom a certain number of fees were set apart. In December, 1841, £25 12s. was divided among the lecturers, and £42 in the March following. In 1845 the amount divided was £102 16s. 1d. A better year was 1850–51, when the fees received amounted to £712, and a surplus of £352 was declared for division. Possibly the influx of students of the new St. Mary's Hospital affected the receipts. In this, as in other balance sheets, a striking feature was the amount of arrears of fees owing. On this occasion it was £368 8s. The next year was better still, for a balance of £425 was reported for division. It was evidently the school's high-water mark, and at this meeting Lane stated his fears for the future.

This booklet is illustrated with excellent reproductions of engraved portraits of Lane and Wilson, and photographs of certificates and medals granted by the school. It is to be hoped that it may soon be made available to the medical public, for its contents are of great interest to all those who care for the history of medicine, as well as to St. George's men.

CONVALESCENT PROVISION IN GREAT BRITAIN.

NEED FOR A GENERAL SURVEY.

CONVALESCENT care has not yet come to be regarded as an essential part of the work of the general hospitals in Great Britain. In ideal circumstances there would probably be provision for the treatment of each patient at every stage of his illness from the onset till his complete restoration to health; but it would be too much to suggest that the hospitals to-day, burdened with responsibilities which are increasing with the growth of population and with the extension of their services to classes formerly treated privately, should regard provision for convalescence as among their primary duties. To a considerable extent the anxieties of hospital authorities with regard to the after-care of patients have been relieved by the establishment, and indeed the general extension, of convalescent facilities by other agencies of various kinds, some independent, many working in close connexion with the hospitals themselves. Thus, while in general there is a definite shortage of convalescent provision, in certain areas it appears to be reasonably adequate. The following analysis may serve as a measure of the problems which must be faced before convalescent facilities in Great Britain can be regarded as sufficient for its needs.

An initial difficulty is presented by the fact that much of the available information lacks precision. The term "convalescent home," for example, covers a variety of institutions, some owned and managed by hospitals as an integral part of their organization, others controlled by friendly societies, trade bodies, or *ad hoc* associations which may receive patients, not necessarily recovering from illness, but merely needing a change of surroundings, simply because they are members or have been recommended by a subscriber. In view of this and other difficulties of classification, the statement printed below may be regarded as giving no more than a rough quantitative summary of existing convalescent accommodation in Great Britain and its relationship to the extent of hospital accommodation and population.

The following table indicates how far the larger hospitals—by which is meant those in London with 70 beds or more, and those elsewhere with 100 beds or more—have made provision for convalescent care. A number of special hospitals have been excluded.

Convalescent Provision in Large Hospitals.

	England and Wales.		Scotland.
	London.	Elsewhere.	
Hospitals having—			
(a) Convalescent homes attached ...	15	35	11
(b) Specific convalescent funds .	5	18	1
Other hospitals	24	65	8
Total	44	119	20

In the category of convalescent homes attached to hospitals are included some actually owned and controlled by the hospitals, and some related to but not owned by them. A convalescent home, for example, may be the property of an independent body, yet give definite preference to patients from a particular hospital. Such preference may be secured by the constitution of the home, or it may be the result of an agreement or merely a tacit understanding between the respective governing bodies. Such loose relationships are probably far commoner than the figures suggest, for they are not necessarily brought out in the information available. Various hospital Saturday funds maintain convalescent institutions for the benefit of their subscribers, and provide a link between the hospital and the convalescent home which is usually as effective as exists in hospitals having a convalescent department of their own. Indeed, the relations between the hospitals and *ad hoc* convalescent institutions, whether controlled by friendly societies or trade bodies or other associations, are usually amicable, and the very looseness of the relation permits of great elasticity in administration and leaves the hospital authorities free to concentrate upon purely internal affairs.

The mere number of specific funds serves only inadequately to indicate the extent to which money is set aside for the needs of convalescents. Practically every London hospital, for example, has at least one "Samaritan Fund" from which the almoner may help to defray the cost of convalescent treatment. The fact that in a recent year one of the larger London hospitals, through this fund, provided more patients with convalescent treatment than another of similar size with a home of its own shows how futile is the attempt to arrive at a just estimate of the extent of convalescent provision merely by considering the number of hospitals with or without convalescent homes or convalescent beds. In point of fact, as the following table illustrates, by far the greater part of the available convalescent accommodation in Great Britain is in institutions not associated with hospitals.

Relationship between Convalescent Provision, Hospital Provision, and Population.

	England and Wales.	Scotland.
Total hospital beds	55,103	8,411
Population per bed	665	680
Total convalescent beds	12,506	1,851
Population per bed	3,029	2,623
Beds not attached to hospitals	10,089	1,270
Beds attached to hospitals	2,417	591
Percentage of total	19.3	31.7
Convalescent beds per 100 hospital beds ...	22.7	22.2

The above figures, though they are based upon incomplete information, present a fairly accurate picture of the situation to-day. It will be seen that in Scotland the proportion both of hospital beds and of convalescent beds to the population to be served is larger than in England and Wales, while the proportion of convalescent beds actually attached to hospitals is considerably greater. It is necessary to add that a survey based upon smaller geographical units would show that the distribution of convalescent facilities is by no means uniform. Approximately 75 per cent. of the convalescent accommodation in Scotland is situated in the Glasgow area, and of the total number of beds over one-half are contained in six large homes relatively inaccessible from Edinburgh, where the shortage of convalescent accommodation has caused some concern in recent years. Irregularities in the distribution of accommodation will probably be found also in the various areas of England and Wales.

A complete study of the problems of convalescent accommodation would involve the collection of information relating not only to the number of convalescent beds available in each area, but also to the manner in which the accommodation is utilized, notably the extent to which it is available for the reception of hospital patients requiring convalescent treatment. It would be valuable, therefore, to know the kind of work each institution undertakes—that is, to have a classification differentiating, for example, between institutions which provide little more than board and domestic attendance from those which have, and require, a trained nursing staff. With such information available for each locality it would be possible to establish a standard by which the optimum convalescent provision for any area might be estimated. It is already possible, largely as the result of the labours of such organizations as the Central Bureau for Hospital Information and King Edward's Hospital Fund, to arrive at a fairly accurate measure of the hospital accommodation required for an area with a given population; it is desirable that similar standards should be worked out with reference to facilities for convalescent treatment. Considerable interest would also attach to the views of those most intimately concerned

as to whether it is desirable for the general hospitals themselves to provide this treatment. As the figures we have given indicate, the existing accommodation has been provided in Great Britain mainly by other agencies, though probably not as the result of any considered policy. The system—if this word may be applied to such a medley of varying relationships—has been built up as nineteenth century towns were, by the inco-ordinated energies of isolated individuals and groups with very little sense of town-planning. Pressing the analogy a stage further, one may say that until a survey has been made no one can tell how far the efforts of the builders will suffice to meet the needs of the country as a whole.

In the *British Medical Journal* of December 3rd, 1927 (p. 1013), we published an address by Mr. Charles Roberts, F.R.C.S., surgeon to the Manchester Royal Infirmary, dealing with surgical convalescence, and putting forward a plea for greater attention to the after-care of patients. Mr. Roberts suggested that there would always be a large population of patients for whom it would be impossible to find accommodation in convalescent homes, and urged that there should be a convalescent department attached to each hospital. His study of the question led him to advocate the establishment of homes, with specially trained staffs, under the control of the hospitals. It would be interesting to examine the position of the hospitals throughout the country with a view to ascertaining how far they fulfil or fall short of his ideals at the present time. As a preliminary to such a study it would be essential to have a complete account of the existing system compiled from a series of regional surveys and supplemented by the views of medical and administrative authorities.

On a national scale a survey could be made by such a body as the Central Bureau for Hospital Information, though only with diffidence would anyone suggest such an addition to its already heavy labours. Much of the work of collecting and classifying data might, however, be profitably undertaken on a regional basis by local organizations, for in many cases hospitals and the convalescent homes which serve them are situated in sufficiently well-defined geographical areas.

Canada.

[FROM OUR CORRESPONDENT IN MONTREAL.]

State Medicine in the Dominion.

THERE is at present no State health insurance in Canada, but frequent references are made to the subject, more especially in the western provinces. There can be no better way of meeting any schemes which may be put forward by the Government than by having a clear idea of general health conditions throughout the country, especially as regards the cost of medical care and the distribution of practitioners in the country districts. These are pressing problems, and they are being closely investigated in the United States. A proposal has recently been made by Dr. J. G. Fitzgerald of the University of Toronto, in the course of the Gordon Bell Memorial Lecture delivered in Winnipeg, that a committee representative of the Canadian Medical Association, the various provincial associations, and the Federal Government should be formed to study such questions. The subject of sickness insurance should come under investigation, and Dr. Fitzgerald made a substantial contribution to the matter by describing the systems existing in the various European countries. While no attempt has yet been made to enact Dominion-wide legislation with regard to State medicine, it is only to be expected that, as preventive medicine assumes wider and wider activities, Government health departments will undertake more and more of the ordinary practitioner's work. This is especially well shown by the development of the provincial travelling clinics in Saskatchewan, which perform tonsillectomies and carry out diphtheria immunization. They were organized originally to deal only with outlying country districts where medical men were few and far between, or even entirely absent, but complaints have been made that occasionally the clinics have intruded on the province of the local practitioners. It seems probable, however, that before long their work will be handed over to the Council of the College of Physicians and Surgeons, on the understanding that the cost to the public will not be greater than at present.

Surgical Research at McGill University.

A gift of 85,000 dollars has been received from the Rockefeller Foundation by the Faculty of Medicine of McGill University for surgical research, and to further co-operation between the surgeons and various laboratory staffs of the University. These staffs include men whose names are well known in research in various fields: Professor Boris Babkin in physiology, Professor J. B. Collip in biochemistry, Dr. John Beattie in anatomy, and Dr. Wilder Penfield in neurological surgery. Well-equipped research laboratories are available for their work both in the University and in connexion with the Royal Victoria Hospital.

Red-water Disease in Cattle.

An interesting paper was published in the *Vancouver Medical Bulletin* of December last on red-water disease, an obscure and, unfortunately, highly destructive condition in cattle. It occurs on a strip of the Pacific coast, extending inland for about sixty miles, from north of the Fraser River into Northern Oregon. Its fatal nature may be gathered from the fact that in eight years it has practically wiped out a herd of sixty-three valuable Holstein Friesians, despite the greatest precautions. The paper offers observations regarding the early stages of the disease which apparently have not been made before. The most striking fact is that the disease is confined to certain well-defined areas. Animals sold from these areas to other localities did not develop "red water," even when they had shown the early symptoms. The disease, however, always proved fatal to animals kept in the affected area. Since the disease first appeared in 1921, what may be called the "incubation" period has become shorter; thus, while at first it was noted that it took two or three years' residence on the farm for an animal to develop bloody urine, the latest cases were found to develop eighteen months after the animal arrived. The first symptom to appear was a failure in milk, and two or three months after the second calving the cows became unthrifty, and showed a tendency to lose flesh. There was no alteration in temperature. A distinct but transitory jaundice, lasting ten or twelve days, with recurrences from time to time, was observed, and it was found that the animals lived from one to three years after first showing bloody urine. Most of the calves born on this farm died from haemorrhagic septicaemia. The few that lived were small for their breed, and eventually developed bloody urine at about the age of 3 years. The conclusion drawn from this study is that "red water" is a deficiency disease for which continued intensive cultivation is responsible. This view is supported by the fact that the animals lived for shorter and shorter periods as the farm grew in age, and that the disease increased in severity. It was also noticed in the winter of 1924–25, when the feed for the animals was purchased from outside, that no new cases developed and the early cases improved. When a return was made to the feed produced on the farm itself, however, the disease reappeared. The later calves would leave "good" home-grown hay to eat their bedding, which was of straw purchased from another district. Nothing unusual in the appearance of the feed could ever be noted; indeed, it appeared to be of unusually good quality. Mineral mixtures of various kinds were tried, but none had any effect on the disease, while frequent examinations of the blood and urine failed to show anything abnormal, and no bacteria or protozoa could ever be discovered. The problem, then, is still unsolved, but recommendations have been made for an exhaustive inquiry to determine the chemical nature of the soil of the farm and of the water, and to make feeding experiments on various groups of cows, using food from affected areas and comparing it with that from other places. A certain amount of experimental work already performed with guinea-pigs on this farm showed that those brought from other quarters and fed on the produce of the farm (clover and carrots), began to die off in about six months. The chief pathological changes found in these animals were in the liver, in which there occurred extensive vacuolation, and probably fatty changes

Medico-legal Aspects of Huntington's Chorea.

An action was recently brought before the courts in Truro, Nova Scotia, which sought to appoint a guardian to a man suffering from Huntington's chorea. The medical evidence on both sides was unanimous that the man was quite competent to direct his own affairs. The case recalls the fact that there are a number of cases of this disease in a certain section of Nova Scotia. Apparently all the patients have been descendants of a brother and sister who came to Nova Scotia from the border of France and Switzerland to escape the persecutions which followed the revocation of the Edict of Nantes. In each of six generations of descendants of these two refugees there have been several cases of the disease, which has been transmitted only by those who actually suffered from it. A similar instance of a hereditary disease whose source has been traced back to France was recently reported by Dr. H. R. Clouston, *at a meeting of the* Montreal Medico-Chirurgical Society, this being hereditary ectodermal dystrophy, involving the hair, skin, nails, and nervous system; it was shown that, although rare according to the literature, the disease is comparatively common in and about Montreal (in the eastern townships). An analysis of six generations showed that 150 known cases had occurred, all traceable back to one family which emigrated from Normandy, where the condition is known to exist. It follows the Mendelian law of hybrids, and in the absence of intermarriage does not appear to have arisen except among French Canadians. Far from being fatal the condition is associated with longevity, but the more advanced cases present an extremely unattractive appearance. Dr. Clouston is pursuing his investigations in the matter with a view to determining the underlying cause, and he has no lack of material in the Province of Quebec.

Poliomyelitis in Manitoba.

The epidemic of poliomyelitis in Manitoba last year seems to have spent itself in October, and so far there has been no outbreak elsewhere. The total number of cases reported by October were 395, with a total of twenty-eight deaths. Convalescent serum was used extensively, with excellent results when given before the onset of paralytic symptoms. A special medical research committee, which is now preparing a report on the epidemic, was formed to deal with the situation, and under its direction convalescent serum was collected. The Winnipeg Medical Society arranged the preparation of articles for the public press on the diagnosis and treatment of the disease.

England and Wales.

Dinner of the Hunterian Society.

A BANQUET was given by the Hunterian Society at the May Fair Hotel on February 14th, to commemorate the 201st anniversary of the birth of John Hunter. After the royal toast and the toast to the memory of John Hunter had been honoured, Dean Inge proposed the toast of "The Hunterian Society," remarking that first among the able men he had known he would put members of the medical profession. The science of psychology made a connecting link between religion and medicine, and if the one could renounce its unfortunate proclivity for magic and the other its materialistic bias, physicians of the soul and of the body might co-operate to the general advantage. Dr. A. Westerman, president of the society, responding, said that the Hunterian Society, which was founded in 1819 for the promotion of the science of medicine, was each year increasing in influence and prosperity. In 1922 there were 152 Fellows; now there were 350. The society mourned the loss of Miss Hunter-Baillie, a direct descendant of John Hunter and an honorary Fellow of the society, who had recently passed away at the age of 85. Mr. A. R. Mortimer Woolf said that in proposing the toast of "The Lord Mayor" he had the choice of two methods, the personal and the impersonal: the first consisted in relating as many facts from the life of their guest as might assist the press in compiling an obituary notice; the latter in making an historical survey of his high office. After recalling the long association of the Hunterian Society with the Corporation of the City of London, the speaker said that if the link was now less than in the past it was due to the excellent work of their guest, the City's medical officer of health. Sir Kynaston Studd, replying to the toast, referred to the days when the élite of the medical profession lived in Finsbury Square and the adjacent district. He was glad that among the most successful meetings of the society were those held in the Mansion House. Mr. Ivor Back, proposing "The Health of the Guests," said that unlike Dick Whittington, whose successor was with them that evening, John Hunter turned his back on Bow Bells, and, migrating from an institution in Smithfield, which Mr. Back was informed still existed, proceeded to one at Hyde Park Corner of whose existence he had no doubt. To be frivolous at the expense of a Lord Mayor was a misdemeanour comparable with simony or barratry or champerty, for which the punishment might be incarceration in the underground dungeons which the Lord Mayor kept below his drawing room. Judging by the frequency with which the streets of London were blowing up, the period of incarceration might not be a very long one. They also had with them the Dean of St. Paul's, whom he had previously caught dining with the medical profession—a habit which seemed undeniable evidence of an esoterically hilarious temperament. Other guests whose health he would propose were Surgeon Vice-Admiral Gaskell, Dr. Walter Carr, Sir Squire Sprigge, and Dr. Willoughby, medical officer of health for the City, whose office was a sinecure, since no one had ever been known to die in the City precincts. Sir Squire Sprigge, Dr. Walter Carr, and Dr. Willoughby, in brief speeches, replied on behalf of the guests. Dr. Carr said, indeed, that he shuddered every time he heard a postprandial orator threaten to say "only a few words," by which he usually meant that he would not only waste time, but encroach upon eternity. In the course of the evening Mr. Tom Clare contributed a number of musical items, which were much appreciated, and the proceedings terminated with the singing of "Auld Lang Syne."

Moorfields.

The annual dinner of past and present students of the Royal London Ophthalmic (Moorfields) Hospital was held at the Langham Hotel on February 7th, with Mr. C. H. Usher, consulting ophthalmic surgeon to the Royal Infirmary, Aberdeen, in the chair; seventy students and guests were present. The various toasts were given by the chairman, Mr. J. H. Fisher, and Sir John Parsons, and were responded to by Sir John Rose Bradford, P.R.C.P., Mr. Theodore Luling, and Air Vice-Marshal David Munro. Among the other guests were Surgeon Vice-Admiral Arthur Gaskell and Professor G. Elliot Smith. During the evening the dean (Mr. Charles Goulden) gave a report on the progress of the institution in 1928. He said that the admission figure of new students had created a record by reaching 134, the previous highest number having been 121 in 1925. The number of students who attended the practice of the hospital was 182. During the twelve months ending October, 1928, 406 lectures had been given by the members of the staff, with the assistance of Mr. Hume, lecturer in anatomy, and Mr. Brinkworth, lecturer in physics. Two students had obtained the diploma F.R.C.S.Ed., while at the final examination for the Diploma in Ophthalmic Medicine and Surgery of the Conjoint Board, 48 of the 59 candidates, and 31 of the 36 successful candidates, had studied at Moorfields. Great success had attended the arrangement for courses by extra-mural lecturers, including Mr. Traquair, who dealt with perimetry, Professor Elliot Smith with the optic connexions of the brain, Professor Hartridge with the resolving power of the eye, and Dr. Kerr with the education of the partially sighted. During the coming term Mr. Traquair will again lecture on perimetry. Mr. Goulden added that applications were frequently made to the hospital by other institutions for house-surgeons and registrars, and by ophthalmic surgeons who required partners and successors. It had been mentioned last year that the school had outgrown its accommodation. Sir William Lister had provided a small additional lecture room, but further space was still needed. A large lecture

room to seat fifty students was required. The library now held only a part of the books, and a reading room for students, to form, perhaps, part of a new library, was needed; and there was a demand for new pathological and bacteriological laboratories. It was hoped that in the building scheme upon which the hospital was shortly embarking room would be found for these urgent requirements of the school.

Eugenics Society.

The twenty-first anniversary of the foundation of the Eugenics Society was celebrated by a dinner on Saturday, February 16th, at the Hotel Rembrandt, London, S.W., with the new president, Sir Bernard Mallet, in the chair. After dinner the Galton Lecture was given by Major Leonard Darwin, only surviving son of Charles Darwin. Major Darwin's address was in substance a review of the work of the Eugenics Society in the past seventeen years during which he had presided over it. A great change had taken place in public opinion. Twenty years ago there were the strangest misapprehensions about the meaning and importance of eugenics. Since then many books had appeared on the subject, some very wise, some very foolish. Progress had been due to the energy of many members of the society and to the generosity of a few. As to the reforms advocated, these had not changed very materially, being based on the principle that like tended to produce like—qualities good and bad in parents being apt to reappear in their offspring. In conclusion, the lecturer discussed some questions of practical policy, and urged the need for a large point of view which embraced the whole of humanity. It was not practicable to aim solely at breeding a eugenic caste on the one hand, and the elimination of mental defectives on the other. The vote of thanks to Major Darwin was proposed by the Dean of St. Paul's, who said that every successful movement had to go through three stages. First of all it was called ridiculous, then it was said to be contrary to religion, and lastly, people said that there was nothing new in it at all. The vote was seconded by Mrs. Neville Rolfe, for many years honorary secretary of the society, and was carried with acclamation. "The Health of the Visitors" was proposed by Professor MacBride, and replied to by Sir Richard Gregory (editor of *Nature*) and Dr. Tate Regan.

Cumberland Infirmary Extension.

The end of its first century of existence finds Cumberland Infirmary well advanced on an ambitious programme of extension, rendered necessary by the heavy increase in the demands made upon it during recent years. A new out-patient department, which has been erected at a cost of upwards of £33,000, was opened on February 7th by the president of the institution, Mr. W. T. Carr. Two wards, situated above the new department, are nearing completion, and it is expected that they will be ready for use by June. The nurses' home is being enlarged, and several of the rooms are already in occupation. A new lift was installed some time back, and renovation of the old buildings is proceeding. We announced on November 1st, 1928 (p. 1007), that plans had been prepared for a new pathological department; it is hoped that arrangements will be made at an early date for the work of its erection to be undertaken. In the programme for the future is the addition of another operating theatre and the provision of isolation accommodation. The new out-patient department includes a dispensary, a reception room for casualties, where minor operations may be performed, and a large waiting hall which communicates with subdepartments for radiology, electrotherapeutics, massage, heliotherapy, diathermy, and dentistry, and a room for examination of the special senses. In addition to these there is a medical department, comprising a consulting room, three adjoining examination rooms, and a clinical laboratory; and, similarly, a surgical department with a consulting room, examination rooms, and an operating theatre. The administration department secures convenient accommodation for the medical and nursing staff. The heating is by low-pressure steam radiators. This new out-patient department is connected with the older part of the Infirmary by a corridor, which will also give access to the two new wards in the course of erection. Mr. Carr, declaring the building open, expressed his belief that it would compare favourably in respect of its equipment and general arrangements with any similar one elsewhere. For the present scheme of extension it is anticipated that a total outlay of at least £70,000 will be required. Despite the rising annual expenditure, a credit balance of over £2,000 was reported as a result of the previous year's working, and it is confidently hoped that there will be an increase in the financial support.

Central Midwives Board.

At a meeting of the Central Midwives Board for England and Wales on February 7th, with Mr. L. H. West in the chair, the reappointment of the following members was announced:

Miss E. E. Greaves, Miss A. Davies, Dr. F. N. Kay Menzies, and Mr. A. B. Maclachlan—representing the Minister of Health.

Mr. L. H. West, representing the Association of County Councils.

Miss E. Richmond, representing the Queen's Institute for District Nursing.

Dr. J. J. Jervis, representing the Association of Municipal Corporations.

Dr. R. A. Lyster, representing the Society of Medical Officers of Health.

The standing committee had under consideration the case of the Wolverhampton District Nurses' Home: as recorded in the *British Medical Journal* of January 19th (p. 127), the Board recently decided to discontinue approval of training at the home. Representations have since been received from the Royal Hospital, Wolverhampton, and the medical officer of health for that town regarding the position, and it has now been decided—in view of the statement that the work of the home is being transferred to the new maternity hospital and that it will be under the control of a committee in no way connected with the committee of the nurses' home—to postpone action pending further investigation. The Board, in connexion with a letter from the Midwives' Institute, adopted a resolution giving its support to the amendment to Section 10 of the Local Government Bill, 1928, set down on behalf of the Institute by Dr. Fremantle, M.P., and decided to send a copy of the resolution to the Minister of Health. Dr. C. F. Brentnall was appointed examiner at the Manchester and Liverpool Centre, and approval was given to Dr. A. G. Newell as a lecturer.

Scotland.

Royal Medical Society of Edinburgh.

THE annual dinner of the Royal Medical Society of Edinburgh was held in the Hall of the Royal College of Physicians on February 14th. Dr. I. G. W. Hill, president of the society, occupied the chair, and the guest of the evening was Dr. G. A. Sutherland, C.B.E. The toast of "The Imperial Forces" was proposed from the chair and acknowledged by Professor F. A. E. Crew, while Dr. A. S. Paterson, in proposing "The City of Edinburgh," referred to the sexcentenary celebrations which are to take place in the city this year, commemorating the charter granted to the city by Robert the Bruce in 1329. The chairman proposed "The Health of the Guest," and Dr. Sutherland, in the course of his reply, mentioned that when he went as a young Scot to Paddington Green Hospital, London, this had been known as the Scottish Hospital, the reason being that two-thirds of its staff were Scots. The connexion with Scotland had since been maintained, for he found that as against 42 residents from all other parts of the world, 35 had been graduates of Edinburgh University. Proposing the toast of "The Royal Medical Society," he wished for it a future as prosperous as it had now enjoyed for nearly two centuries past. Dr. C. P. Beattie proposed the toast of "The Sister Professions," and the Very Rev. C. L. Warr, Dean of the Thistle, replied for the Church, and Lord Salvesen for the profession of law.

Gift to Glasgow University.

At a meeting of the Glasgow University Court on February 14th Principal Sir Donald MacAlister, who presided, reported that he had received from the Lord Rector, Mr. Stanley Baldwin, a cheque for £1,000, to be devoted to some object within the purview or control of the medical faculty of the University. The gift is a grant from a sum of money which Lord Beaverbrook had placed at the disposal of the Prime Minister in gratitude for the escape of Lord Beaverbrook and his associates in a recent motor accident. Attention was drawn at the same meeting to the large number of applications received for admission to first-year classes in medicine at the University of Glasgow. It was pointed out that normally there was accommodation for 180 students in the first year, and the suggestion was made that the limit of enrolment might be fixed at 200. A great number of applications had been received from overseas, including applications from seventy-nine Americans to commence the study of medicine at Glasgow University.

Physical Welfare of Glasgow Students.

At a meeting of the general council of the University of Glasgow an ordinance was considered which provided for an addition of 10s. 6d. annually to the matriculation fee, so that this sum should be specially earmarked for the physical welfare of students. Principal Sir Donald MacAlister, who presided, mentioned that the initiative in this project came from the students themselves more than two years ago. The three universities of Edinburgh, St. Andrews, and Glasgow had taken up separate ordinances on this matter, and believed that the students were right in holding that the matriculation fee should be increased in order that the common interest in physical welfare might be represented by a common levy. The University Court in Glasgow had already established a university students' fund, which was intended to foster all the activities of the students of this nature. That fund would still be available, and had practically meant that the University Court would pay £1 for every £1 of the students' contribution. The attempt that had been made some years ago to raise a fund for the general welfare of the students had been supported in many quarters and now approached £100,000. By this means they had acquired the athletic grounds, built a pavilion and spectators' stand, and were now engaged in the erection of a students' union. The annual finance had, however, to be provided for, and as these interests were in one aspect or another common to all students, the students themselves were anxious that all alike should share in helping towards their annual maintenance. In laying aside a certain sum for the physical welfare of students, the University Court had designed that the entrance fees should be lowered, and this had been done.

Glasgow Hospital Needs.

A meeting of the Court of Contributors of Glasgow Royal Infirmary was held in the Merchants' House, Glasgow, on February 11th. Lord Provost Sir David Mason presided, and remarked that the Royal Infirmary, during the 134 years of its existence, had occupied an indispensable place in the community of Glasgow. Its requirements were, however, increasing, and there was still need for more widespread generosity in supporting this institution, despite the fact that recently there had been a gratifying increase in the subscriptions and donations from employees. The claims of hospitals must not be forgotten during times of abnormal distress, because the work of the Infirmary was specially great during such times. Mr. James Macfarlane, chairman of the Board of Managers, said that the most important event of the previous year had been the completion of the reconstruction scheme inaugurated in 1897, which had absorbed £271,000 of the Infirmary's free funds. It must be remembered that they had lost the income on this £271,000, and had also incurred additional costs for maintenance, although they were now provided with one of the finest hospitals in the kingdom. The free capital was now entirely exhausted, and the work of the institution depended almost wholly on what was received from year to year. Other institutions connected with the Infirmary, such as a new ophthalmic institution and the convalescent hospital at Canniesburn, were also urgently required. For the annual revenue of the Infirmary an additional sum of £20,000 per annum in subscriptions was needed in order to give the directors confidence to go on as they were doing. This should be a trifling sum if divided over the population of Glasgow, and even if divided over the number of persons already subscribing annually to the Infirmary, it amounted to an extra gift of less than £1 per head per annum.

Central Midwives Board for Scotland.

At the examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, and Dundee, there were 106 candidates, of whom 87 passed. Of the successful candidates, 24 were trained at the Royal Maternity Hospital, Edinburgh; 35 at the Royal Maternity Hospital, Glasgow; 9 at the Elsie Inglis Memorial Hospital; 4 at the County Maternity Hospital, Bellshill; 3 at Barshaw Maternity Hospital; 3 at Motherwell Maternity Home; 2 at the Eastern District Hospital; 3 at the Govan Maternity Cottage Hospital; 1 at Dundee Royal Infirmary; 2 at the County and City of Perth Royal Infirmary; 1 at the Edinburgh Lying-in Institution, and the remainder at various recognized institutions.

Nursing Home for Selkirk.

At a meeting of the town council of Selkirk on February 11th, Provost Ballantyne announced that two residents in the district had presented sums of £2,000 and £1,000, with the object of purchasing Viewfield Nursing Home, in the neighbourhood of the town. The purchase price was about £3,500, so that this nursing home had virtually been presented to the town by the generosity of these two donors.

Ireland.

Child Welfare in the Irish Free State.

WITH the object of promoting certain amendments of the Children's Act, 1908, a deputation composed of members of various organizations recently visited the Ministry of Local Government, where it was received by the Secretary in the unavoidable absence of the Minister. The amendments suggested were as follows. (1) That effect should be given to the recommendation of the report of the Poor Law Commission—namely, that the law should be strengthened in the direction of prevention by the introduction of affiliation orders. (2) That homes with attached maternity and probationary departments should be established to accommodate the mother and child for as many months, up to a year, as might be considered necessary; that it should not be lawful for the owner of any private house or nursing home to take a maternity case for profit unless it has first been licensed by the local authority; the premises must be open for inspection and a register be kept of the names and addresses of the mothers of all children born in such home, and the names and addresses of all persons into whose care such children are given when leaving. (3) That any person acting as agent in putting a child under the age of 7 out to be nursed should be equally liable with the person who receives the infant. The person acting as agent must forward to the local authority a receipt stating the amount received for placing the infant, and the person who receives the child may be required to attend before a divisional magistrate or district justice to satisfy the justice whether any fee has been given, and that the transaction was for the benefit of the child. (4) That no child should be sent to any person for maintenance for reward unless and until the local authority for the district gives a certificate that the person who is to have charge of such an infant is a fit and proper person, and that the premises are suitable in every respect. (5) That any offender against the Children's Act may be prosecuted within, say, twelve months after the commital of such offence or continuing offence, notwithstanding the provisions of any Act or Acts to the contrary. There was agreement as to the necessity for additional safeguards, but the discussion revealed

certain difficulties which more stringent regulations or changes in the substance of the law would create. The deputation undertook to give the matter further consideration and to prepare a supplementary memorandum.

Immunization in the Treatment of Diphtheria.

Dr. E. F. Stephenson, chief medical officer of the Department of Local Government and Public Health, in a public statement in connexion with the prevention of diphtheria, has said, although it was thought inadvisable to make too strenuous efforts to persuade parents to have their children immunized, it was felt that, where the disease threatened to become epidemic, the parents should be informed that active immunization provided a safe, practicable, and effective method of prevention. It was recognized that in order to ensure success immunization schemes for the eradication of diphtheria should be conducted on systematic lines, under the supervision and guidance of a county medical officer of health, and consequently the appointment of these officers was especially urged where diphtheria had established a footing. The distribution of the disease, as brought to the notice of the department in the year ended March 31st, 1928, is shown in the following table of reported cases: Carlow 8, Cavan 27, Clare 32, Cork 201, Donegal 26, Dublin 49, Galway 82, Kerry 33, Kildare 16, Kilkenny 12, Queen's County 5, Leitrim 4, Limerick 13, [illegible] 38, Mayo 8, Meath 3, Monaghan 9, [illegible] 14, Sligo 5, Tipperary 14, Waterford 15, Westmeath 7, Wexford 50, Wicklow 10. Out of a total of 698 reported cases, 505 occurred in rural districts and 193 in urban districts, of which 23 per cent. and 43 per cent. respectively were attributed to Cork County rural and urban districts. With the exceptions of Cork County (Kinsale and Passage West), Galway, County Louth (Dundalk), and the county boroughs, the disease, apart from occasional small outbreaks, has been of infrequent prevalence. In the isolated rural areas the sporadic occurrence of diphtheria can probably best be countered by the swabbing of contact cases and the isolation of carriers. Milk is a recognized vehicle of infection of diphtheria. In accordance with the recommendation of the Interdepartmental Committee, the provisions of the Public Health (Pneumonia, etc.) Regulations are being revised, and applied to diphtheria amongst dairy employees.

Correspondence.

THE BEHAVIOUR OF THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF.

SIR,—Dr. Harrington Sainsbury has raised the question as to what exactly happens to the artery and the circulation under the sphygmomanometer cuff during compression (*British Medical Journal*, February 2nd, p. 191). It is some years since I pointed out that the effects can be studied under the microscope with the help of the Roy and Graham Brown apparatus. The experiments which I now describe should, I think, be included in any course of practical physiology, so that the medical student may know the principles underlying the measurement of blood pressure in man.

The Roy and Graham Brown apparatus is in principle a sphygmomanometer. It consists of a small cylindrical brass chamber floored with glass and enclosed above by a sheet of areolar tissue, which can conveniently be got from a rabbit. This is transparent, and so easily distensile that very little error arises from the pressure required to distend it. A diameter of 3 mm. suffices for the upper end of the chamber. Into the chamber there is sealed a side tube which connects by a T-piece with (1) a water manometer and (2) a tube for raising the pressure in the chamber. The chamber has attached to it an upright carrying a horizontal arm, which can be raised or lowered by a screw adjustment. To this arm is attached by sealing-wax a small piece of glass (cut from a microscope slide) broad enough just to cover the top of the chamber. There is also attached a sheet of cork on which a frog can be fastened so that part of the web of one foot is spread over the areolar tissue which covers the top of the chamber.

The frog is anaesthetized with urethane. The brain can first be crushed with forceps so that the animal is dead to the law. The urethane is a 25 per cent. solution; 0.3 c.cm. or more, according to size of frog, is injected under the skin of the back. The web is arranged so that its free edge lies over the middle of the top of the chamber. By means of the screw adjustment the glass plate is then lowered down so that it just comes in gentle contact with the web, a film of water being interposed. The apparatus is then put under a microscope, using a 1/2-inch objective, and the circulation observed. There must be no interference with the normal circulation, which appears fast, continuous, unpulsatile. On gently raising the pressure by blowing down the tube, one sees that the flow in many of the capillary loops at the edge of the web ceases, and the blood is expressed from these, while it continues to flow in capillaries where the resistance is less. It generally takes about 5 or 6 cm. of water to effect this. The same pressure usually suffices just to produce a pulsatile effect in the adjacent network of terminal arterioles, and those capillaries and venules through which the flow still continues. The true capillary pressure is then under 5 to 6 cm. of water, for this pressure suffices to stop the flow in many, and so bank up the pressure to that in the arteriole which is supplying them, some of the kinetic energy being changed into static. This same pressure, if momentarily applied, suffices to check momentarily and to reverse the flow in the terminal arterioles. If the pressure be now raised further the flow ceases in more and more capillaries and venules, and finally in all and in the arterioles. As the flow becomes restricted to fewer and fewer capillaries it becomes more and more pulsatile, till finally only a spurt of corpuscles gets through on each systole, and then with a little more pressure this stops, and the arterioles are flattened and emptied, the blood in them being expressed. During the expression and blanching of the web the flow in the arterioles is reversed. On letting down the pressure step by step one reaches the point when the systolic pulse just drives some corpuscles through the arterioles. This pressure, usually about 12 to 15 cm. of water, indicates the systolic pressure in the main arteriole which supplies the terminal arterioles, for banking up results from stopping the flow. The true mean pressure in the terminal arterioles approximates to that in the capillaries, and is given by the pressure which, when applied momentarily, checks the flow, and when maintained just produces a visible sign of pulsation. To shut up one of the main arterioles in the web it may require a pressure of some 20 cm. of water; as banking up occurs this is the systolic pressure in the artery which supplies it. To produce a pulse, or momentarily to check the flow, a pressure is usually required about half this amount. It is to be concluded, then, that about half the systolic pressure in such an artery is spent in maintaining the velocity of flow in the terminal network of vessels. The energy is so used up in overcoming frictional resistance in this network that in the capillaries the mean pressure is not more than 5 to 6 cm. of water.

A sphygmomanometer cuff to fit the frog's thigh can be made out of a piece of a toy balloon (sausage-shaped). This is closed at each end, and has a glass tube inserted and tied into the middle. An outer cover for the rubber bag is afforded by a piece of thin waterproof material, a hole being made in this for the passage of the glass tube. The tube is connected by means of a T-piece to a water manometer and a tube for raising the pressure. The cuff is snugly applied round the thigh, and two pieces of tape gently drawn round and tied over it so as to confine the expansion of the rubber bag effectively, but not so as to interfere with the circulation. Observation of the web under the microscope will show that the circulation remains normal. In place of feeling the pulse at the wrist, or listening to it in the brachial artery below the cuff, as in the case of man, the circulation in the web of the frog is observed under the microscope and pressure noted when the blood flow ceases. It will be seen that as the pressure is raised in the cuff the flow in the terminal network of arterioles, capillaries, and venules becomes pulsatile and slower until the flow ceases in more and more capillaries, and only comes through in pulses; finally it ceases to pulse through the main arteriole.

It takes about 30 to 40 cm. of water to stop the flow in the sciatic artery in the thigh; as banking up occurs this is the systolic pressure in the aorta which supplies the sciatic artery. Similarly in man, the systolic pressure measured by the arm cuff is not that in the brachial artery, but in the axillary artery which supplies it. About half the stopping pressure produces a pulsatile flow in the terminal web, and this may, I think, be taken as near to the true mean pressure in the sciatic artery. In the case of man if the cuff on the arm be connected with a recording tambour, and the pressure raised until pulsation becomes distinct, that pressure will closely approximate to the true pressure. It is not possible to observe in the web the effect

of a momentary check applied to the sciatic artery, because after the flow in the sciatic artery has been stopped the arteries below continue to squeeze blood on through the terminal network. To measure the systolic pressure it is best to raise the pressure till the pulse stops, wait till the flow stops in the web, and then relax the pressure until the pulse just begins to drive some corpuscles through the arterioles in the web. To carry out these observations the large edible frogs which can be obtained from Hungary are the most suitable. In such a frog another cuff can be placed round the tarsus; then the pressure can be measured at the thigh, the tarsus, and the web, and the drop in pressure mapped out. Dr. Gaddum inserted a cannula for me in the sciatic artery of a big frog on one side, and this was connected with a mercury manometer. The systolic pressure so measured corresponded within 1 mm. of mercury with that measured by the cuff on the other thigh.

An experiment of interest is to keep a pressure of, say, 20 cm. of water in the cuff on the thigh, and observe the congestive effect on the web; the arterioles, capillaries, and veins all become wider, the flow is retarded and becomes pulsatile in place of being smooth and continuous. To shut up the terminal arterioles in the web will now require a pressure a little over 20 cm. of water, for the pressure has banked up to that owing to reduction of flow brought about by the compressive action of the cuff.

Be it noted that less than this pressure suffices to empty some of the loops at the edge of the web, for blood can be expelled into capillaries and vennles which are not yet filled to distension. So, too, in man, when the pressure in the cuff on the arm is maintained, say, at 40 mm. of mercury, the pressure rises in the large veins below the cuff to this height, as blood comes from the arterioles through the wider paths, where resistance is least. But it is not the case that all the capillaries in the arm are filled to distension at this pressure. The mere feel of the skin will show that this is not so; moreover, blanching of a small area can be produced by a much less pressure. The blood can be pushed from one part of the terminal network into another which is not yet full to distension. It would take a long time for all the capillary network to open out and fill up, and before this happens the feeling of painful pressure becomes intolerable. Moreover, the frictional resistance is so increased by the 40 mm. of mercury pressure in the cuff that the flow only continues through the wider pathways of least resistance, and ceases in tortuous pathways of higher resistance. All this can be observed in the frog's web when a pressure is maintained in the cuff on the thigh.

Measurements made in the frog's web, tongue, liver, glomeruli of kidney, mesentery, edge of mouse's ear, muscular wall of abdomen of mouse, liver of mouse, bat's wing, and vascular area of 2 to 3-day-old chick embryo show that the capillary pressure is very low, equivalent to a very few millimetres of mercury, and does not suffice for the theories of filtration which for so long have been in vogue. The measurements of capillary pressure made in the skin of man (1) by insertion of a micro-pipette, (2) by finding the pressure which just stops bleeding from a small cut, confirm this statement. The capillary networks are surrounded with tissue cells and the whole is confined within a capsule in the case of a gland, in the case of a limb within aponeurosis and skin. The capillary pressure, small as it is, is then counterbalanced by the tissue fluid pressure. The interchange between tissue cells and blood in the capillaries is brought about, then, through the membrane of the capillary wall, not by filtration, but by the varying state of physico-chemical equilibrium of the tissue cells and the blood. The changes, such as oedema, ascribed to back pressure are not really due to back pressure, but to lessened flow and consequent want of oxygen and disordered metabolism, which leads to the tissue cells pulling fluid out of the capillaries to dilute poisonous products. So, too, in inflammation, the products of injury cause fluid to be pulled out by the tissue cells, just as mucus is secreted to dilute an injurious substance in the mouth. The circulation is designed to bring a flow of blood to the tissue cells with only the thin capillary wall interposed; these cells pull out while the blood pulls in materials until the two come into equilibrium. It is an error to suppose that the heart by its force drives blood, say, to the glomeruli of the kidney or to the ciliary body of the eye, and there filters out fluid. Observation shows that no adequate filtration pressure exists in the glomeruli. A more likely hypothesis is that the cells of the proximal convoluted tubules, by secreting crystalloids into the capsules, pull water out of the capillaries of the glomeruli. How living cells secrete into and absorb from the circumambient medium we do not know.—I am, etc.,

National Institute for Medical Research, Hampstead, N.W., Feb. 12th. LEONARD HILL.

SIR,—I am much disappointed by Sir James Barr's letter respecting my paper under the above heading. I am sure he would be the last to misrepresent the drift of an argument, yet when he says that I try "to establish by inference" what *he* "thought was long since proved by experiment—namely, that colloids are practically incompressible"—and ends his letter by "it will require *something more* [my italics] than Dr. Sainsbury's inference to convince me that the brachial artery remains full when submitted to a pressure sufficient to obliterate the pulse at the wrist"—when he does this, will not the *inference* drawn by the reader of his letter be that the sum and substance of my paper is concerned with a proving of that which is already well established? Certainly it will not encourage him to look into my argument.

Sir, I was guilty of no such futility; indeed, I did not even *infer* the incompressibility of the colloids of the arm; I assumed it, took it for granted, and based my argument upon it. In a paragraph of ten lines, beginning "On *a priori* grounds," I disposed of this physical aspect of the problem, appending a footnote reinforcing my assumption with the authority of the emeritus professor of physics at University College, London, Professor A. W. Porter, F.R.S., respecting the relative incompressibility of liquids and colloids, for which there are no data available.

It will not be necessary for me to look up Sir B. W. Richardson's paper; I have had ample personal experience of the incompressibility of muscle when expressing its juice for patients. Sir James wants "something more than my *inference*" in order to be convinced; well, my paper works out at seven full pages of reprint as against ten lines allotted to my assumption (his inference)—and I am in despair.

The fact is that my argument is not touched upon except in one brief, to me cryptic, sentence: "With the armlet it is difficult or impossible to raise the capillary pressure to that of the arteries, therefore the blood in the compressed artery will move on to the distal capillaries." But when the pressure of the armlet upon the artery becomes equal to the intra-arterial pressure, inasmuch as these two forces are in opposition, will there not be stasis? And if there is stasis, will not the pressure upon the blood in the artery and the blood in the capillaries become equal, since the incompressible *extra* vascular tissues must transmit *equally* throughout their substance the pressure to which they are subjected?—I am, etc.,

London, W.1, Feb. 15th. HARRINGTON SAINSBURY.

ASTHMA.

SIR,—The general practitioner is naturally inclined to be more interested in the clinical aspect of this subject, which may help him to relieve some of the most distressing symptoms of asthma, than in the pathological platitudes of the specialist, and it seems that Dr. Harrington's suggestion (February 9th, p. 271) is distinctly worthy of consideration. We are told that there is no one cure for asthma, because the causes are so varied that it is impossible that one treatment should control them all. But there is one point which seems neglected, and that is, that there is one characteristic common to *all* the causes—namely, their power of causing irritation, whether it be bronchitis, nasal polypi, indigestion, or any other of the numerous irritative influences. A further point is that these influences do not cause asthma—of themselves—but only when a further pathological condition is present—namely, a hypersensitiveness of the bronchial mucous membrane, and it seems to me that the research is

directed to the investigation of these irritative influences somewhat to the neglect of the other condition necessary for the production of asthma—namely, the hypersensitiveness or tendency to spasm of the bronchial tissue.

From this point of view it may be of some interest to note the extremely successful results of the treatment of eleven cases of angina by diathermy in my own experience, and many similar results by other workers (*vide* articles in the *Lancet*, October 10th, 1926, by Dr. John Hay and others). Recognition that one of the most potent results of the diathermy current is its marked antispasmodic effect led me to apply it in several cases of asthma with very satisfactory results.

Some three weeks ago a medical man suggested its trial in the case of his wife, who for two years had suffered from asthma of an extreme type. She had been under a well-known London specialist, and later, for four months, under a provincial specialist; not the slightest impression had been made. Her dyspnœa was practically continuous, and was greatly increased by any walking—even a few yards—a sudden noise, or a bright light, or any other external stimulus caused distressing spasms. Such sleep as she obtained was only possible with nightly inhalations of oxygen by a special inhaler. Her condition seemed practically hopeless.

Diathermy was applied and the distress caused by the effort of undressing subsided in a few moments; at the conclusion she was more "comfortable" than she had been for many months. This "comfort" lasted some four hours. Each application since (three times weekly) has resulted in marked increase of relief, both in amount and duration, until after nine treatments her condition has almost incredibly improved. She can now walk round her garden with no distress and has had no actual spasms for some days. She sleeps soundly—seven to nine hours each night—without any oxygen inhalations, and altogether her condition has entirely changed in every way.

I should like to disarm the obvious criticism that one, or even three or four cases, proves nothing definite, that the improvement may not last, and so on, by pointing out that nothing else hitherto tried in two years has had any effect at all, and that it has yet to be proved that the improvement is not going to last.

I merely wish to suggest that this method of treatment is one which may justify further investigation in view of the following considerations: (1) the extreme severity of the case itself; (2) the failure of any remedy hitherto applied (and their name is legion) to effect any improvement; (3) the practically immediate and continued, rapid, and progressive response to the treatment up to date; (4) the fact that diathermy was not applied empirically, but in view of its well-known powerful antispasmodic effect.—I am, etc.,

J. NEWTON DYSON, M.R.C.S., L.R.C.P.

Southport, Lancs, Feb. 7th.

SIR,—I should like to sound a note of warning with regard to nasal operations in cases of asthma. One might be led to surmise from Sir James Dundas-Grant's letter on January 26th (p. 179) and Dr. Barnett's letter of February 9th (p. 271) that there was great hope for the asthmatic in nasal operations. So long ago as 1899 a discussion on asthma in relation to the upper air passages, in which many of the leading rhinologists took part, showed that the general opinion as regards the prospect of obtaining permanent relief by nasal operations was anything but hopeful.

The late Sir Felix Semon summed up his experience of the nasal treatment of asthma by placing the cases in three classes: (1) lasting success obtained, a very small percentage; (2) temporary benefit, a comparatively large percentage; (3) no success at all, a very large percentage. To these Sir StClair Thomson suggested the addition of a fourth class—namely, cases considerably damaged by intranasal treatment (report of the proceedings of the Laryngological Society of London, May 5th, 1899). Since that time much evidence has accumulated to confirm the above summary.

Mr. Frank Coke pointed out, in his letter on February 9th (p. 270), that relief of asthma might follow any surgical operation, such as the removal of the appendix or gall-bladder, and in the same way a nasal operation might bring temporary relief, especially if there is profuse haemorrhage. To my mind the chief source of error comes from the belief that asthma is due to a bronchial muscular spasm set up reflexly by nasal disease, instead of being, as I am convinced, a vasomotor neurosis, dependent upon the general sympathetic nervous system. In certain cases it is advisable to perform a submucous resection, or other operation, to enable the nasal passages to function properly, but do not let us deceive ourselves that such operations are in themselves going to cure asthma. The one point I would emphatically insist upon is that no extensive operation should be undertaken for the removal of nasal polypi in an asthmatic subject with a low blood pressure. These are the patients, I find, who cannot take aspirin, and the complete removal of polypi in these will almost certainly be followed by most disastrous results so far as the asthma is concerned.—I am, etc.,

London, W.1, Feb. 12th. ALEXANDER FRANCIS.

"THE NATURE OF DISEASE."

SIR,—With reference to Sir Humphry Rolleston's kind notice of my work in his Huxley Lecture (February 16th, p. 283), I would like to take this opportunity to say that he has not quite accurately represented my views, and I should be grateful if you would allow me to give an outline of my thesis.

In my opinion there is only one disease, and this the result of the worsting of the host's protective mechanism by the invader. The host's main protective mechanism is the protein in the plasma, which is in the form of colloid particles all negatively charged. Disease is the result of the altered chemico-physical changes to which these protein particles are subjected by the invader. The action of the invader is the same, be it a physical agent, a chemical agent, or a micro-organism. Hence there is only one invader. The protein particles are constituted much as is a solar system, where there is a protein nucleus corresponding to the sun and various adsorbed constituents such as amino-acids, fat, urea, uric acid, sugar, salts, and electrons corresponding to the planets. In the solar system the planets are kept in relationship to the sun by gravity and in the protein particle by water. The water is continuous with the water in the liquid portion of the plasma, which contains in true solution most of the adsorbed constituents bound to the protein nucleus in a colloid complex in the particle. The higher the concentration of the water in the particle the more complex becomes the colloid combination between the adsorbed constituents and the protein nucleus, and vice versa. The adsorption of the constituents by the protein nucleus varies according to the position in the particle taken up by the constituents—that is to say, the colloid combination between the protein nucleus and urea is greater than that between the protein nucleus and sugar. The various adsorbed constituents, so long as they remain in true solution, can be detected as such, but when they enter into colloid combination with the protein nucleus they lose their identity as simple substances, and the more so the more readily they are adsorbed.

When the protein particles are attacked by the invader they lose some of their water, or undergo dehydration, and in the process the various adsorbed constituents are liberated in the order of the relationship they bear to the protein nucleus: first electrons, then calcium, sugar, urea, and so on. The liberation of the various planets renders them ionic. The liberation of the electrons are concerned there is a change into heat energy which manifests itself as fever. Protein particles being sent into true solution are adsorbed by other particles whose surface tension may have been already lowered by the invader, in which case the particles increase in size, agglutinate, and tend to become precipitated. This change is referred to as hydration because the particles take up more water and more complex colloid combinations are formed between the protein sun and its planets, thereby lowering the percentage of the adsorbed constituents in true solution. It thus comes about that dehydration is the main change in the acute stage of disease and hydration in the chronic stage. As dehydration is due primarily to the loss of electrons, drugs having a conductor action are called for, and this is the rationale of manganese butyrate in boils, "sup 36" in influenza and pneumonia, "sum 468" and mercurochrome in streptococcal infections, arsenic, bismuth, and mercury in syphilis, etc. In chronic dehydration hydrators are required, and this is the action of insulin in diabetes.

But there is just as much sugar in the blood after as before a dose of insulin. Hydrated protein particles are best broken up and dispersed by dehydrators, hence the use of glucose and oxygen injected subcutaneously in shock, contramine in rheumatism, etc.

The more hydrated protein particles become the greater grows their independence, a fact which tends to make them behave as foreign bodies. Indeed, cancer is the result of such a change occurring in cells. If the hydrated protein particles are too large to circulate they collect in the pericapillary lymphatic vessels and capillaries, where, acting as foreign bodies, they subject the protein particles constituting the protoplasm of the cells of the organ, where the precipitation takes place, to the same changes as the host's main resistance underwent by the invader in the first instance. It is in this way that most of the organic manifestations of disease arise. All the changes the protein particles undergo can be verified, and full data are given in my two volumes of *The Nature of Disease*, published in 1924 and 1927 respectively.—I am, etc.,

London, W., Feb. 16th. J. E. R. McDONAGH.

PYORRHOEA ALVEOLARIS.

SIR,—From time to time letters appear in medical periodicals, as in your issue of January 26th, and statements are made at meetings of learned societies imputing to the toothbrush the causation of pyorrhoea. They are always based on theory and unsupported by evidence. The truth is exactly the reverse—lack of friction causes gingivitis; intelligent use of the toothbrush will both prevent and cure it, as can be proved by anyone who cares to make the experiment.

Primitive man lived perforce on food sufficiently hard and tough to exercise a detergent action on his teeth and gums. With the invention of cooking and the advance of civilization his food became softer, probably never so soft as to-day; as a result the mouth is not cleaned by the action of chewing, soft debris collects about the necks of the teeth, and the gum margin becomes infected, inflamed, and puffy. Because the gum is tender and bleeds easily there is a tendency to choose the softest food, and the sufferer purposely avoids touching the sore spot with the toothbrush; so matters go from bad to worse.

The remedy for all this is friction—massage is the fashionable word nowadays—and in no way can it be applied so effectively as with a toothbrush. The finger is too large; it cannot reach between the teeth, and its use fills up rather than cleanses any interdental spaces which may exist.

A well-shaped brush, with bristles fairly long and not too closely set, and with a longer tuft at the end, can be made to reach practically everywhere, inside and outside. If the gums are tender a "soft" brush—bristle, not badger hair—should be used at first, giving place shortly, as the gums get harder, to "medium." I see no advantage in the very hard brushes advised by some. The patient should be instructed to use the brush after meals—that is, at bedtime, after breakfast, and, if possible, after lunch; it should be impressed upon him that it is more important to brush the gums than the teeth, and that bleeding or tenderness is a sign that friction is needed, not an indication for its avoidance. The teeth should be brushed in the direction of their length, as one would brush the teeth of a comb. Beginning on the gum margin, the bristles should be thrust well between each pair of teeth, both from the outside and especially from the inside, and this is where the tuft comes in. Horizontal brushing, confined as it usually is to the buccal surfaces of the teeth, is of little use, and if vigorous may, with the addition of a dentifrice, cause serious abrasion of their surfaces.

Your correspondent says that the toothbrush "is always septic, and frequently filthy." Septic it is certainly, for we live in a septic world, but filthy it need not and should not be; the mouth is a septic cavity, and probably specially resistant to infection. To insist on sterility of the toothbrush would be to bar its use to 99 per cent. of the population.

For at least thirty years I have advocated the thorough use of the toothbrush, with results invariably good and sometimes almost startling in their success. Soreness and bleeding cease, the gum becomes hard and pink, and the incidence of caries is greatly reduced, often to vanishing point. The only objection that can be proved against it is that it occasionally causes some baring of the buccal surfaces of the roots; but, even if extensive, this is of little moment, since the gums remains healthy and the teeth firm. Common salt, either in powder or solution, may be used with advantage on the brush, but friction is the essential thing and the adjuvant matters little. To leave salt on the upturned brush when not in use is the simplest method of obtaining a high standard of cleanliness.

An ounce of practice is worth a ton of theory, and I invite all sceptics to put my statements to the proof. The results will be in exact proportion to the care exercised. Doubtless, Nature never intended the use of a toothbrush, and when mankind adopts a more natural diet it may not be necessary; but meanwhile, rightly used, it remains the most effective weapon we possess against dental disease.—I am, etc.,

London, W.1, Feb. 11th. J. H. BADCOCK.

AMAUROTIC FAMILY IDIOCY.

SIR,—I thank Dr. Stenhouse Stewart for his reply to my letter (February 9th, p. 270) with further data on the pedigree of amaurotic family idiocy. I agree that if there were originally an equal number of DD and DR types the disease would gradually become rarer throughout successive generations, but assuming that the disease has always been a rare one (which seems much more likely), and that in the first place the DD's enormously outnumber the DR's, so that the chances are that the few existing DR's will all marry DD's, the proportion of each remains the same in all succeeding generations.

In other words, if the total number of the population remains constant, each marriage resulting in two children, the DD-DD marriages result in two DD children, and the DD-DR marriages in one of each. Only when the rare chance occurs of a DR-DR union does the disease reappear, and as the affected RR dies in infancy the proportions of various types remaining in the race is negligibly affected thereby.

As to Dr. Stewart's suggestion of repeated in-breeding leading to the development of recessive factors, this is, of course, an interesting possibility which may be a factor in this disease. I merely wish to maintain that there is nothing in the evidence so far supplied which is against a simple Mendelian transmission.—I am, etc.,

Sheffield, Feb. 13th. ROBERT PLAIT, M.D., M.R.C.P.

SIR,—Dr. Stenhouse Stewart's queries about the pedigree of amaurotic family idiocy (January 19th, p. 101) interested me greatly as, since 1923, I have had three cases of this rare disease through my hands.

In April, 1923, I showed before the Children's Section of the Royal Society of Medicine (*Transactions*, Royal Society of Medicine, No. 16) a classical case of Tay-Sachs disease in a non-Jewish child, aged 20 months. Careful search failed to reveal any possibility of any Jewish ancestry in the family for three generations; the parents, however, were first cousins. The second case occurred in a Jewish child with no family history of consanguinity or of mental deficiency for at least two generations. The third case, in a Jewish baby, I showed at the last meeting of the Children's Section on January 25th, and it is still under my care. There is no history in the family of consanguineous marriage or of mental deficiency, but, in view of the recent interest raised, I shall take this opportunity of a more thorough interrogation and investigation.

My own view is that immediate heredity is not an important etiological factor.—I am, etc.,

London, W.1, Feb. 12th. LEOPOLD MANDEL, M.D., M.R.C.P.

TREATMENT OF CANCER BY LEAD.

SIR,—I have read Professor Blair Bell's letter in your issue of February 2nd (p. 224), and cannot enter into further discussion of phrases removed from their context. The report of the St. Bartholomew's Hospital Committee on the lead treatment of cancer is available for those who wish to continue to study the subject. (*St. Bartholomew's Hospital Reports*, 1928, and *Proceedings of the International Cancer Congress*, 1928.) It is for the medical profession to decide whether the continuation of the Liverpool method of treatment is justifiable or not.—I am, etc.,

London, E.C.1, Feb. 17th. J. BASIL HUME.

STANDARDS OF PUERPERAL MORBIDITY.

SIR,—My attention has been drawn to the correspondence which is taking place in your columns concerning the proper standard for estimation of puerperal morbidity. It fell to my lot to bear a considerable part in the establishment of the morbidity index of the British Medical Association, and I shall be obliged if you will permit me to state my recollections of its inception.

At the Annual Meeting of the British Medical Association held at Leicester in the year 1905 I read a paper on puerperal morbidity before the Obstetrical Section, presided over by Dr. Herbert Spencer.[1] In this communication I condemned in no measured terms the then prevalent morbidity index which fixed the limit of health at an arbitrary figure of 100.4° F. This archaic index of morbidity originated in pre-aseptic days, when it was believed that the puerperium must be accompanied by abnormal temperature, because of the greater metabolic processes which were occurring during that time. In practice it produced disastrous results, as patients, because of it, were discharged from hospital as normal with a temperature of 100.3° F., and without any reference to the pulse rate. Instead, I suggested that all temperatures above 99° F. within a certain period, recorded on three consecutive bi-daily readings, and accompanied by a pulse rate of over 90, should be considered morbid.

As a result of this communication the Association appointed a representative committee to study the question and furnish it with a report. The committee assembled at Dr. Herbert Spencer's house in London in the autumn of the same year, and I do not believe that the subject was ever examined by a more representative body. After considerable discussion they rejected the index which at that time was in use in the Rotunda Hospital, and I believe is still employed there. Instead, they unanimously agreed to the following:

"A temperature above 100° F., occurring on any two occasions between the end of the first thirty-six hours and the end of the eighth day, recorded on a half-minute thermometer, which should be placed in the mouth for a period not under three minutes."

All deaths were to be included as morbid, and abortions excluded, for the reason that hospitals operating in densely populated industrial areas had to admit an undue proportion of septic cases of this kind, thus making it impossible to compare their standard with that of other institutions more favourably situated. The reason for omitting the first thirty-six hours was to eliminate the fear of the temperature reaction being considered abnormal. The eighth day was named to permit hospitals which discharged their normal patients on this date to bring their results into line.

The committee attached great importance to details for recording temperature. The neglect of these details would greatly favour the careless attendant who was under loose supervision. The provisions of this standard were slowly read out by the chairman, and recorded by each one of us present at the meeting. It soon afterwards appeared in my annual report of the Rotunda Hospital, and our temperatures have been recorded by this standard ever since. It has been extensively adopted in the maternity hospitals of Great Britain and Ireland, and is largely in use in Canada and the other British dominions. In these circumstances I suggest that a very careful search be made through the files of the *British Medical Journal*, and if this is done I have no doubt that a full summary of the committee's findings will be brought to light. The Association spent a considerable sum in the assembly of this special committee, and it would be quite disastrous if this money had been expended to no purpose.

In conclusion, I feel at a loss to understand how a "continuous temperature" could be recorded for twenty-four hours. Conceivably it could happen in a State-endowed hospital by leaving a domestic thermometer in the rectum for twenty-four hours, watched over by a large staff for whom some sort of work must be found. The absurdity of estimating a "continuous temperature" in district practice need only be mentioned to be appreciated.—I am, etc.,

E. H. TWEEDY, M.D., F.R.C.P.I.,
Former Master of the Rotunda Hospital.

Howth, co. Dublin, Feb. 13th.

[1] *British Medical Journal*, 1905, ii, 704.

*** The full text of the report drawn up by the Association's Committee on Puerperal Morbidity was published in the *Supplement* on May 19th, 1906.

IMMEDIATE ENUCLEATION FOR QUINSY.

SIR,—The memorandum by Mr. Wallace on the above subject, published on February 16th (p. 296), is of more than usual interest to practitioners and surgeons alike. As a general surgeon I have, of course, much less experience in this class of case than the writer, but my experiences may be worth recording.

Since 1926 I have performed all dissections of tonsils under local anaesthesia, following the technique which I learnt at the Mayo Clinic, where many thousands of such operations are conducted annually. In 1927, after perfecting the technique to my own satisfaction, I dealt with more than seventy hospital patients from the waiting list, treating them as out-patients, and operating in a dental chair. Some four cases can be completed in an hour, and returned home within half an hour of operation, after being inspected and given tea. Haemorrhage is far less marked by this method, and only three cases required ligature. All the patients were again inspected in four days' time, and only one reported haemorrhage, which had subsided by the time the doctor had arrived.

Three cases of quinsy have been treated in the same way, and the anaesthesia was quite satisfactory in spite of the inflamed state of the pharynx. The quinsy itself is not incised, but, after the tonsil has been removed, the pus slowly reaches the fossa, and is gently mopped away by gauze swabs. The other tonsil is not touched unless similarly affected.

As compared with the older methods of treatment the following example will show the comparatively easy convalescence from the condition.

In March, 1927, I was summoned to see a university "don" in his rooms with a large left quinsy and a temperature of 102° F.; he was endeavouring to correct examination papers "against the clock." A sedative was given, and two hours later under local anaesthesia the affected tonsil was dissected out, the pain and tension being immediately relieved. He returned at once to bed, and completed his work on the following day; two days later he conducted a viva voce examination as if nothing untoward had happened.

From time to time there may be cases presented to us in which a general anaesthetic is contraindicated. I have used this method with advantage on hospital and sanatorium patients suffering from subacute rheumatism and pulmonary tuberculosis respectively. The technique dates back to before 1915, and is described fully in the *Mayo Clinic Papers*, vol. viii, 1916, pp. 895–897.

As hitherto the necessary instruments have been obtainable only in America, Messrs. Thackray of Leeds have copied them for me, and have them available on application.—I am, etc.,

HUGH WHITELOCKE.

Oxford, Feb. 16th.

PERSONAL HYGIENE AND MEDICAL EDUCATION.

SIR,—Professor W. W. Jameson's paper in the *Journal* of October 27th, 1928, on "The teaching of hygiene," with your leading article thereon (pp. 733 and 759), add to the ever-increasing call for placing health in the foreground of education, both scholastic and professional. The latter *is possible scholastically only when every child knows and* follows the laws of personal health, when every girl learns

mothercraft, when every mother has due ante-natal and maternity treatment, when every baby is properly fed and hygienically cared for, and when all the rising generation enter the battle of life with balanced development—physically, mentally, and morally. True education means "health for the body, truth for the mind, and goodness for the spirit." Professionally the requirements are that all medical students and nurses should be taught to think and act in terms of health rather than of the diagnosis and treatment of disease, to know at least as much about the mens sana and the corpus sanum as of materia medica, and to busy themselves rather with the prevention than the cure of disease.

Scholastically, much has been done in England under wise leaders—among whom Sir George Newman stands out pre-eminent. But how much remains to be done is shown in the calls for reform that are increasingly being made at practically every educational conference. It is something that England now leads the world in these matters, but it is almost as depressing as it is inspiring to find how much of fundamental importance remains to be done. Professionally we are much farther behind even than scholastically. If the professions, ancillary as well as medical, are to be equal to the new requirements, the authorities—from the lowest licensing body to the General Medical Council itself—must readjust their requirements accordingly. It is not enough that a few specially enterprising and capable individuals go out of the beaten track of practice. As Professor Jameson says, "there is no more important person in the ranks of health workers than the general practitioner—he must be given a correct sense of proportion when a medical student." There may be differences of opinion as to how best to revise an at present overloaded curriculum; there can be none as to the necessity for this fundamental reform in attitude and practice.

As lecturer for many years in the Melbourne medical school, I devoted in my textbook (1914) 208 pages to personal, and 119 to public health; as Victorian delegate to the jubilee congress of the Royal Sanitary Institute (1926) I made a special plea for the "health education of the individual," and two explanatory letters were given prominence in the *Times* of July 10th and August 8th of that year. In the *Transactions* of the Australasian Association for the Advancement of Science (Hobart, January, 1928) will be found two further papers—namely, "Health and education" and "A magna charta for the child." Further, I have presented a report to our cabinet and Parliament on "Maternity and child welfare, health, and education," and a circular letter to authorities has recently been issued by the Society for the Health of Women and Children of Victoria, of which I am president.

Are we, the medical profession, not, as Sir George Newman well and eloquently puts it, "at the door of opportunity," and is it not our duty "to lay the foundations for a new epoch"?—I am, etc.,

J. W. SPRINGTHORPE, M.A., M.D.

Melbourne, Dec. 6th, 1928.

"THE RIGHT TO PRACTISE."

SIR,—Registration under the Medical Acts in this country is of such importance that I wish to controvert the assertion of Dr. A. G. Newell (January 19th, p. 134) that: "A duly qualified medical practitioner is not bound to register."

All medical degrees and diplomas are not registrable in this country, but only those which are contained in Schedule A of the Medical Acts, and those who do not "register," whether their degrees or diplomas are registrable or not, are as restricted in practice as the unqualified charlatan. They cannot hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service or in emigrant or other vessels, or in any hospital infirmary, dispensary, or lying-in hospital not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health (Medical Act, 1858, Section 36).

There is only one exception to this, and that is that any person *not* a *British* subject who has passed the regular examinations entitling him to practise medicine in his own country may act as resident physician or medical officer of any hospital established exclusively for the relief of foreigners in sickness, provided that such person is engaged in no medical practice except as such resident physician or medical officer (Medical Act, 1859, Section 6).

Further, the unregistered person is not recognized in law as a duly qualified medical practitioner. He cannot issue a death certificate; he cannot sue for his fees; he cannot give evidence as an expert medical witness in any court of law in this country, nor issue any medical certificate which will be accepted in such court of law.

Registration is the seal which distinguishes the duly or legally qualified medical practitioner from all others, and an unregistered person is therefore not a legally or duly qualified medical practitioner so far as this country is concerned, and cannot practise as such.—I am, etc.,

Hyde, Jan. 26th. J. GORDON MACQUEEN, M.B.

THE CENTENARY FUNCTIONS AT CAIRO.

SIR,—To your report of some remarks made by me at the recent meeting of the Council relative to the centenary of the Faculty of Medicine of the Egyptian University,[1] will you allow me to add a word or two expressive of the feeling of admiration of the British delegates—for I feel sure the others share my feeling—in respect of the life and vigour of the Faculty of Medicine and of the Kasr-el-Aini Hospital, Cairo? In an atmosphere clearly scientific, the hum of activity was arresting. The impression grew in passing from department to department.

Nor can I close without publicly expressing the high appreciation by the delegates of their extremely kind and thoughtful reception by colleagues on the faculty and hospital. While our gratitude is due to everyone who contributed to the successful celebrations, there can be no invidiousness if I ask you to place on record our special indebtedness to the genial and distinguished dean, Mr. F. C. Madden, O.B.E., M.D., F.R.C.S., and the honoured subdean, Professor Ali Bey Ibrahim, M.B.E., whose admission to the rank of Honorary Fellow of the Royal College of Surgeons of England by the President of the College formed a striking scene in a wonderful setting.—I am, etc.,

University of Edinburgh, Feb. 18th. R. W. PHILIP.

Obituary.

SIR BERTRAM WINDLE, M.D., LL.D., F.R.S.,

Professor of Anthropology and Lecturer on Ethnology, Toronto.

DEEP regret will be evoked in all parts of Ireland by the announcement of the death, at the age of 70, of Sir Bertram Windle, professor of anthropology and ethnology at the University of Toronto, which took place in Toronto on February 14th.

Sir Bertram Coghill Alan Windle was born in England on May 8th, 1858, his father being the Rev. S. A. Windle, B.D., vicar of Market Rasen, Lincolnshire, and his mother daughter of Admiral Sir Josiah Coghill, Bt. His parents removed to Ireland, and he was educated at Kingstown and Repton Schools, later proceeding to his professional studies at Dublin University. He acquired many academic distinctions, among them M.A.Dublin (with first-class honours in natural science at B.A.); M.D., B.Ch.Dublin (having taken first place at M.B.); D.Sc.Dublin; M.Sc.Birmingham; LL.D., R.U.I., Birmingham, and Boston; Ph.D. (hon. causa) Rome; D.Sc. (hon.) Marquette University; and F.R.S. He was made a Knight of St. Gregory the Great by Pope Pius X in 1909, and was created knight after the New Year's Honours List in 1912. In 1891 he was appointed dean of the medical faculty of Queen's College, Birmingham; he later became professor of archaeology, and in 1904 president of University College, Cork. During the fifteen years of his presidency Sir Bertram contributed to the development of the College and enjoyed world-wide eminence as a scholar and writer. In October, 1919, he

TREATMENT OF CANCER BY LEAD.

SIR,—I have read Professor Blair Bell's letter in your issue of February 2nd (p. 224), and cannot enter into further discussion of phrases removed from their context. The report of the St. Bartholomew's Hospital Committee on the lead treatment of cancer is available for those who wish to continue to study the subject. (*St. Bartholomew's Hospital Reports*, 1928, and *Proceedings of the International Cancer Congress*, 1928.) It is for the medical profession to decide whether the continuation of the Liverpool method of treatment is justifiable or not.—I am, etc.,

London, E.C.1, Feb. 17th. J. BASIL HUME.

STANDARDS OF PUERPERAL MORBIDITY.

SIR,—My attention has been drawn to the correspondence which is taking place in your columns concerning the proper standard for estimation of puerperal morbidity. It fell to my lot to bear a considerable part in the establishment of the morbidity index of the British Medical Association, and I shall be obliged if you will permit me to state my recollections of its inception.

At the Annual Meeting of the British Medical Association held at Leicester in the year 1905 I read a paper on puerperal morbidity before the Obstetrical Section, presided over by Dr. Herbert Spencer.[1] In this communication I condemned in no measured terms the then prevalent morbidity index which fixed the limit of health at an arbitrary figure of 100.4° F. This archaic index of morbidity originated in pre-aseptic days, when it was believed that the puerperium must be accompanied by abnormal temperature, because of the greater metabolic processes which were occurring during that time. In practice it produced disastrous results, as patients, because of it, were discharged from hospital as normal with a temperature of 100.3° F., and without any reference to the pulse rate. Instead, I suggested that all temperatures above 99° F. within a certain period, recorded on three consecutive bi-daily readings, and accompanied by a pulse rate of over 90, should be considered morbid.

As a result of this communication the Association appointed a representative committee to study the question and furnish it with a report. The committee assembled at Dr. Herbert Spencer's house in London in the autumn of the same year, and I do not believe that the subject was ever examined by a more representative body. After considerable discussion they rejected the index which at that time was in use in the Rotunda Hospital, and I believe is still employed there. Instead, they unanimously agreed to the following:

"A temperature above 100° F., occurring on any two occasions between the end of the first thirty-six hours and the end of the eighth day, recorded on a half-minute thermometer, which should be placed in the mouth for a period not under three minutes."

All deaths were to be included as morbid, and abortions excluded, for the reason that hospitals operating in densely populated industrial areas had to admit an undue proportion of septic cases of this kind, thus making it impossible to compare their standard with that of other institutions more favourably situated. The reason for omitting the first thirty-six hours was to eliminate the fear of the temperature reaction being considered abnormal. The eighth day was named to permit hospitals which discharged their normal patients on this date to bring their results into line.

The committee attached great importance to details for recording temperature. The neglect of these details would greatly favour the careless attendant who was under loose supervision. The provisions of this standard were slowly read out by the chairman, and recorded by each one of us present at the meeting. It soon afterwards appeared in my annual report of the Rotunda Hospital, and our temperatures have been recorded by this standard ever since. It has been extensively adopted in the maternity hospitals of Great Britain and Ireland, and is largely in use in Canada and the other British dominions. In these circumstances I suggest that a very careful search be made through the files of the *British Medical Journal*, and if this is done I have no doubt that a full summary of the committee's findings will be brought to light. The Association spent a considerable sum in the assembly of this special committee, and it would be quite disastrous if this money had been expended to no purpose.

In conclusion, I feel at a loss to understand how a "continuous temperature" could be recorded for twenty-four hours. Conceivably it could happen in a State-endowed hospital by leaving a domestic thermometer in the rectum for twenty-four hours, watched over by a large staff for whom some sort of work must be found. The absurdity of estimating a "continuous temperature" in district practice need only be mentioned to be appreciated.—I am, etc.,

E. H. TWEEDY, M.D., F.R.C.P.I.,
Former Master of the Rotunda Hospital.

Howth, co. Dublin, Feb. 13th.

[1] *British Medical Journal*, 1905, ii, 704.

*** The full text of the report drawn up by the Association's Committee on Puerperal Morbidity was published in the *Supplement* on May 19th, 1906.

IMMEDIATE ENUCLEATION FOR QUINSY.

SIR,—The memorandum by Mr. Wallace on the above subject, published on February 16th (p. 296), is of more than usual interest to practitioners and surgeons alike. As a general surgeon I have, of course, much less experience in this class of case than the writer, but my experiences may be worth recording.

Since 1926 I have performed all dissections of tonsils under local anaesthesia, following the technique which I learnt at the Mayo Clinic, where many thousands of such operations are conducted annually. In 1927, after perfecting the technique to my own satisfaction, I dealt with more than seventy hospital patients from the waiting list, treating them as out-patients, and operating in a dental chair. Some four cases can be completed in an hour, and returned home within half an hour of operation, after being inspected and given tea. Haemorrhage is far less marked by this method, and only three cases required ligature. All the patients were again inspected in four days' time, and only one reported haemorrhage, which had subsided by the time the doctor had arrived.

Three cases of quinsy have been treated in the same way, and the anaesthesia was quite satisfactory in spite of the inflamed state of the pharynx. The quinsy itself is not incised, but, after the tonsil has been removed, the pus slowly reaches the fossa, and is gently mopped away by gauze swabs. The other tonsil is not touched unless similarly affected.

As compared with the older methods of treatment the following example will show the comparatively easy convalescence from the condition.

In March, 1927, I was summoned to see a university "don" in his rooms with a large left quinsy and a temperature of 102° F.; he was endeavouring to correct examination papers "against the clock." A sedative was given, and two hours later under local anaesthesia the affected tonsil was dissected out, the pain and tension being immediately relieved. He returned at once to bed, and completed his work on the following day; two days later he conducted a viva voce examination as if nothing untoward had happened.

From time to time there may be cases presented to us in which a general anaesthetic is contraindicated. I have used this method with advantage on hospital and sanatorium patients suffering from subacute rheumatism and pulmonary tuberculosis respectively. The technique dates back to before 1915, and is described fully in the *Mayo Clinic Papers*, vol. viii, 1916, pp. 895–897.

As hitherto the necessary instruments have been obtainable only in America, Messrs. Thackray of Leeds have copied them for me, and have them available on application.—I am, etc.,

Oxford, Feb. 16th. HUGH WHITELOCKE.

PERSONAL HYGIENE AND MEDICAL EDUCATION.

SIR,—Professor W. W. Jameson's paper in the *Journal* of October 27th, 1928, on "The teaching of hygiene," with your leading article thereon (pp. 733 and 758), add to the ever-increasing call for placing health in the forefront of education, both scholastic and professional. The best is possible scholastically only when every child knows and follows the laws of personal health, when every girl learns

mothercraft, when every mother has due ante-natal and maternity treatment, when every baby is properly fed and hygienically cared for, and when all the rising generation enter the battle of life with balanced development—physically, mentally, and morally. True education means "health for the body, truth for the mind, and goodness for the spirit." Professionally the requirements are that all medical students and nurses should be taught to think and act in terms of health rather than of the diagnosis and treatment of disease, to know at least as much about the mens sana and the corpus sanum as of materia medica, and to busy themselves rather with the prevention than the cure of disease.

Scholastically, much has been done in England under wise leaders—among whom Sir George Newman stands out pre-eminent. But how much remains to be done is shown in the calls for reform that are increasingly being made at practically every educational conference. It is something that England now leads the world in these matters, but it is almost as depressing as it is inspiring to find how much of fundamental importance remains to be done. Professionally we are much farther behind even than scholastically. If the professions, ancillary as well as medical, are to be equal to the new requirements, the authorities—from the lowest licensing body to the General Medical Council itself—must readjust their requirements accordingly. It is not enough that a few specially enterprising and capable individuals go out of the beaten track of practice. As Professor Jameson says, "there is no more important person in the ranks of health workers than the general practitioner—he must be given a correct sense of proportion when a medical student." There may be differences of opinion as to how best to revise an at present overloaded curriculum; there can be none as to the necessity for this fundamental reform in attitude and practice.

As lecturer for many years in the Melbourne medical school, I devoted in my textbook (1914) 208 pages to personal, and 119 to public health; as Victorian delegate to the jubilee congress of the Royal Sanitary Institute (1926) I made a special plea for the "health education of the individual," and two explanatory letters were given prominence in the *Times* of July 10th and August 8th of that year. In the *Transactions* of the Australasian Association for the Advancement of Science (Hobart, January, 1928) will be found two further papers—namely, "Health and education" and "A magna charta for the child." Further, I have presented a report to our cabinet and Parliament on "Maternity and child welfare, health, and education," and a circular letter to authorities has recently been issued by the Society for the Health of Women and Children of Victoria, of which I am president.

Are we, the medical profession, not, as Sir George Newman well and eloquently puts it, "at the door of opportunity," and is it not our duty "to lay the foundations for a new epoch"?—I am, etc.,

J. W. SPRINGTHORPE, M.A., M.D.

Melbourne, Dec. 6th, 1928.

"THE RIGHT TO PRACTISE."

SIR,—Registration under the Medical Acts in this country is of such importance that I wish to controvert the assertion of Dr. A. G. Newell (January 19th, p. 134) that: "A duly qualified medical practitioner is not bound to register."

All medical degrees and diplomas are not registrable in this country, but only those which are contained in Schedule A of the Medical Acts, and those who do not "register," whether their degrees or diplomas are registrable or *not*, are as restricted in practice as the unqualified charlatan. They cannot hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service or in emigrant or other vessels, or in any hospital infirmary, dispensary, or lying-in hospital not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health (Medical Act, 1858, Section 36).

There is only one exception to this, and that is that any person *not* a *British* subject who has passed the regular examinations entitling him to practise medicine in his own country may act as resident physician or medical officer of any hospital established exclusively for the relief of foreigners in sickness, provided that such person is engaged in no medical practice except as such resident physician or medical officer (Medical Act, 1859, Section 6).

Further, the unregistered person is not recognized in law as a duly qualified medical practitioner. He cannot issue a death certificate; he cannot sue for his fees; he cannot give evidence as an expert medical witness in any court of law in this country, nor issue any medical certificate which will be accepted in such court of law.

Registration is the seal which distinguishes the duly or legally qualified medical practitioner from all others, and an unregistered person is therefore not a legally or duly qualified medical practitioner so far as this country is concerned, and cannot practise as such.—I am, etc.,

Hyde, Jan. 25th. J. GORDON MACQUEEN, M.B.

THE CENTENARY FUNCTIONS AT CAIRO.

Obituary.

SIR BERTRAM WINDLE, M.D., LL.D., F.R.S.,

Professor of Anthropology and Lecturer on Ethnology, Toronto.

DEEP regret will be evoked in all parts of Ireland by the announcement of the death, at the age of 70, of Sir Bertram Windle, professor of anthropology and ethnology at the University of Toronto, which took place in Toronto on February 14th.

Sir Bertram Coghill Alan Windle was born in England on May 8th, 1858, his father being the Rev. S. A. Windle, B.D., vicar of Market Rasen, Lincolnshire, and his mother daughter of Admiral Sir Josiah Coghill, Bt. His parents removed to Ireland, and he was educated at Kingstown and Repton Schools, later proceeding to his professional studies at Dublin University. He acquired many academic distinctions, among them M.A.Dublin (with first-class honours in natural science at B.A.); M.D., B.Ch.Dublin (having taken first place at M.B.); D.Sc.Dublin; M.Sc.Birmingham; LL.D., R.U.I., Birmingham, and Boston; Ph.D. (hon. causa) Rome; D.Sc. (hon.) Marquette University; and F.R.S. He was made a *Knight of St. Gregory the Great* by Pope Pius X in 1909, and was created knight after the New Year's Honours List in 1912. In 1891 he was appointed dean of the medical faculty of Queen's College, Birmingham; he later became professor of archaeology, and in 1904 president of University College, Cork. During the fifteen years of his presidency Sir Bertram contributed to the development of the College and enjoyed world-wide eminence as a scholar and writer. In October, 1919, he

accepted an invitation to contribute a course of lectures at the University of Ontario, later being made professor of cosmology and anthropology in St. Michael's College, and special lecturer on ethnology, University of Toronto. During his stay in Canada he became a prominent figure in the intellectual life of the Dominion, where his death will be regarded as a great loss.

In the course of his career Sir Bertram was a member of the General Medical Council (representing the University of Birmingham from 1900 to 1905, and the National University of Ireland from 1914 to 1920), president of the Irish Technical Association, commissioner under the Irish Universities Act of 1908, member of the Consultative Committee of the Board of Education, Commissioner of Intermediate Education, Ireland, member of the Irish Convention, 1917–18, and examiner in anatomy in the Universities of Cambridge, Aberdeen, Glasgow, Durham, and to the Royal College of Physicians, London, and the Royal College of Surgeons, Ireland. In 1920 he was Norton Memorial Lecturer to the American Anthropological Institute. He was considered an unrivalled authority on comparative anatomy and certain branches of archaeology, and his writings in connexion with Catholic philosophy won him a widespread reputation.

Sir Bertram was a member of the British Medical Association, occupying the position of vice-president of the Section of Anatomy and Physiology when the Association held its Annual Meeting in Birmingham in 1890, and that of vice-president of the Section of Anatomy and Histology when it met in London in 1895. Of his publications, which were many, it is possible to mention but a few to indicate the variety of his interests: *A Manual of Surface Anatomy; The Proportions of the Human Body; Life in Early Britain; The Wessex of Thomas Hardy; The Prehistoric Age; Facts and Theories; The Catholic Church and its Reactions with Science;* and many scientific papers and articles.

His first wife was Madeline, daughter of the late Mr. W. Hudson of Birmingham, and in 1901 he married Miss Edith Mary Nazer. The deepest sympathy will be extended to his relatives in their bereavement.

DR. ARTHUR GORDON MCKAY MURDOCH, whose death occurred on February 5th at the age of 25, was a member of the staff of the Glasgow Corporation Bacteriological Laboratory. He received his early education at the High School of Glasgow, and studied medicine at the University there, graduating M.B., Ch.B. in 1925, and obtaining the diploma in public health two years later. For a year he served as a demonstrator in the Public Health Department of the University, and eighteen months ago joined the Corporation bacteriological staff. He was a member of the British Medical Association. A colleague writes: Engaged as Dr. Murdoch was upon a phase of public health work which is unseen for the most part by the public, his thoroughness and efficiency as a bacteriologist were of much importance to the medical practitioners of the city and to the citizens, especially in connexion with diphtheria, enteric fever, and tuberculosis. To the investigation of these diseases he devoted himself unremittingly, giving of his best for the public weal. He was greatly esteemed by his colleagues, who found in him an ever-obliging, conscientious, and reliable fellow worker.

HOWARD VIVIAN ALEXANDER GATCHELL, who died in Salisbury, Southern Rhodesia, on November 25th, 1928, following an operation for duodenal ulcer, was the son of the Rev. J. H. Gatchell, D.D., co. Tyrone, Ireland. Before the war he held a post under the Middlesex County Council. Dr. Gatchell served in France and rose to the rank of major in 1917; on demobilization he was for a time on the medical staff of the Ministry of Pensions, and in 1920 was appointed medical inspector of schools under the Southern Rhodesian Government. He showed great enthusiasm for his work, which took him all over the colony, where, it is no exaggeration to say, he was known to and respected by everyone. His annual reports were always instructive, and many improvements in the health conditions of the younger Rhodesians owe their inception to his recommendations. Only those who have taken part in the development of a young colony can understand how much his influence counted for. In his spare time Dr. Gatchell built up an extensive private practice in ophthalmology. As a man Gatchell was a typical Irishman; his cheery personality rose supreme over all the hard-ships and hazards of his journeys on the veld, and his ready wit made him a companion to be enthusiastically welcomed wherever he went. He was a prominent member of the Mashonaland Branch of the British Medical Association, and was the representative of the Branch at the Annual Meeting in Cardiff last year. His death occurred only a fortnight after his return from leave. Dr. Gatchell is survived by a widow and two sons, for whom much sympathy is felt.

DR. HENRY HERBERT LLOYD PATCH, who died on February 7th, in his fifty-ninth year, had long been in practice as an anaesthetist in Liverpool, where he was held in high esteem by his colleagues. He received his medical education at St. Thomas's Hospital, and in 1893 obtained the diplomas M.R.C.S.Eng., L.R.C.P.Lond., and L.S.A. For a period of about eighteen months afterwards he acted as assistant house-surgeon at the Devon and Exeter Hospital, where his grandfather and great-grandfather had been surgeons. He was subsequently resident medical officer to the Ramsgate General Hospital and Seamen's Infirmary, and visiting surgeon to the Ramsgate and St. Lawrence Royal Dispensary. Dr. Patch commenced general practice at Chudleigh, removing later to London. About eight years ago he settled in Liverpool, where he devoted himself entirely to the administration of anaesthetics, in which he had unusual ability. He was honorary anaesthetist to the Royal Infirmary, the Royal Southern Hospital, the Dental Hospital, and the Liverpool Medical Research Organization, and anaesthetist to the Ministry of Pensions Hospital at Knotty Ash, being also joint lecturer on anaesthetics to the Liverpool University Clinical School. He was a member of the Liverpool Medical Institution. A colleague writes: Dr. Patch's quiet confidence and wonderful disposition were of great advantage to those with whom he worked. His most unselfish character and kindness of heart won for him many friends, and his death will be an irreparable loss to them all. The last three years of his life were harassed by illness, but he carried out his duties with magnificent fortitude, both in the hospitals to which he was attached and in private practice. He is survived by his widow and one son.

We regret to record the death of DR. ROBERT KINNEAR HAY GILLESPIE, at his residence, Headingley, Leeds, on February 13th. Dr. Gillespie had a distinguished career as a student at Glasgow University, gaining many awards of merit, including the John Hunter medal in surgery and graduating in 1915 with the degrees of M.B., Ch.B. After serving as a resident medical officer on the staff of the Royal Infirmary, Glasgow, he joined the Royal Army Medical Corps and was posted to Salonika, where he served until he was invalided home in 1918. Appointed on his return to the East Leeds War Hospital, he was subsequently transferred to the War Hospital at Beckett's Park, Leeds. He joined the staff of the Ministry of Pensions when the latter hospital came under the control of the Ministry in 1920 and remained in that service until 1927. In September of that year he entered into private practice in the Headingley district of Leeds, and rapidly gained the confidence and esteem of a large circle of patients. In the army, and later in the Ministry of Pensions, Dr. Gillespie gave unstintingly of his abounding energy, and many disabled ex-service men will remember him, not only as a skilful and attentive surgeon, but also as a friend and adviser in many matters. His chief hobby was engineering, and his manipulative dexterity was manifest, not only in the operating theatre, but also in the training workshops of the various hospitals to which he was attached. His strong and engaging personality brought him many friends who sincerely regret his death at the early age of 37, a death which was precipitated by disregard of himself in the interests of his work. He married in 1922, and is survived by his widow.

We regret to learn of the death, at the age of 66, of FRANCIS XAVIER DA COSTA, F.R.C.S.Eng., L.R.C.P.Lond., L.M. and S.Bombay, which occurred on December 23rd, 1928, at Bangalore, Southern India. After receiving his early education at St. Xavier's College, Bombay, and graduating in medicine and surgery at Bombay University, he entered Charing Cross Hospital, and obtained the diplomas of the English Conjoint Board in 1888. For some time he served as house-surgeon to Charing Cross Hospital, proceeding to the Fellowship of the Royal College of Surgeons, England, in 1890. Subsequently he held appointments as house-surgeon to the St. Peter's Hospital for Stone, and surgical registrar to Charing Cross Hospital. During this period he earned a high reputation as a coach in medical and surgical subjects. On his departure for India in 1894 he received from his teachers, fellow students, and pupils in England tokens of their appreciation of him as man and colleague. After some years' practice in Goa he proceeded in 1908 to Bangalore, where he soon commanded an extensive practice. In 1915 he was placed in charge of St. Martha's Hospital, where he worked until some five months before his death. He was highly respected for his professional skill, his genial manner, and ready sympathy. The Apostolic delegate in India, the Bishop of Mysore, and other high officials of the Roman Catholic Church have referred to the death of Dr. da Costa as a loss sustained by the whole diocese of Mysore. He leaves a widow, who is also a member of the medical profession, three sons, and three daughters.

The following well-known foreign medical men have recently died: Dr. JEAN SICARD, a prominent neurologist and professor of medical pathology in the Paris faculty of medicine; Inspector-General DELORME, formerly director of the medical school at the *Val-de-Grâce Military Hospital* and president of the Académie de Médecine, aged 82; Dr. JAMES BADAL, formerly professor of clinical ophthalmology at Bordeaux, aged 89; Dr. LÉOPOLD DANDOIS, emeritus professor of clinical surgery at Louvain and formerly president of the Belgian Royal Académie de Médecine; Dr. ERNESTO TRICOMI, professor of clinical surgery at Palermo; Professor HEINRICH WINTERBERG, a Vienna cardiologist; and Dr. PAUL SILEX, extraordinary professor of ophthalmology of Berlin, aged 71.

CORRECTION.

PROFESSOR T. WARDROP GRIFFITH desires to correct a slip in the obituary notice of Dr. J. E. Eddison published in the *Journal* of February 16th (p. 327). In the fourth line of the second paragraph, for "the first William Hey" read "the second William Hey."

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on February 16th the degree of Doctor of Medicine (D.M.) was conferred on L. J. Barford.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on February 16th the following medical degrees were conferred:

M.B.—E. G. Recordon.
B.CHIR.—I. C. C. Tchaperoff.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on February 14th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

The secretary reported the death, on January 28th, of Mr. Victor G. Plarr, M.A., Librarian of the College since 1897. The following vote of condolence was passed:

> The Council hereby express their deep regret at the death of Mr. Victor Gustave Plarr, and their very sincere sympathy with Mrs. and Miss Plarr in their bereavement. The Council do also record their appreciation of Mr. Plarr's services to the College as librarian, a post which he held with faithfulness and unfailing courtesy during the long period of thirty-one years. The Council recognize that the reputation of the library has been worthily maintained during Mr. Plarr's term of office, and that the good order in which it has been kept during large additions and several extensions bears witness to his able direction and to the care and attention which he devoted to the duties of his office.

The Library Committee was requested to consider and report to the Council upon the steps to be taken with the object of filling up the vacant office of librarian, and upon what alterations, if any, it would be desirable to make in Section 27 of the Standing Rules relating to the office.

The Diploma of Fellowship was granted to Russell Claude Brock, who had complied with the regulations.

Diplomas of Membership were granted to 143 candidates, and Diplomas in Public Health were granted jointly with the Royal College of Physicians to 37 candidates. (The names of the recipients of the diplomas were printed in the report of the meeting of the Royal College of Physicians, published in our issue of February 9th, p. 276.)

The President reported that he had appointed Mr. R. P. Rowlands as Bradshaw Lecturer for the ensuing year.

Mr. Ernest W. Hey Groves was appointed Hunterian Orator for the year 1930.

The secretary reported that from information recently received from Canada it appeared probable that there would be a sufficient number of candidates to justify a Primary Examination for the Fellowship being held at Toronto this year, that the dates of the examination had provisionally been fixed for August 6th and 7th for the written examination and August 9th and 10th for the viva voce examination, and that Professors William Wright, Le Gros Clark, Lovatt Evans, and John Mellanby had accepted the nomination to conduct the examination, Professor J. B. Leathes having found it not possible for him to act.

The President reported that he had received a letter from the Prime Minister enclosing a cheque for £1,000 as a grant to this College from the sum of money placed at the Prime Minister's disposal by Lord Beaverbrook in gratitude for his and his associates' escape in a recent motor accident: the sum to be expended either as capital or interest for the furtherance of medical knowledge—for example, research studentships, contributions to scientific equipment or to the library, and not to be used for any purpose of a routine character or one which should be met out of ordinary income. The Council referred this matter to the Museum Committee for their advice.

A letter was read from Sir James Berry resigning his seat in the Council, such resignation to take effect at the end of the College year in June. The resignation of Sir James Berry was accepted with regret.

The President reported that an election of four Fellows into the Council would take place on Thursday, July 4th, at 11 a.m., in the vacancies occasioned by the retirement in rotation of Sir H. J. Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley, and by the resignation of Sir James Berry; that notice of the election would be given to the Fellows by advertisement and by circular on March 9th; that March 18th would be the last day for the nomination of candidates; and that a voting paper would be sent on April 2nd to every Fellow of the College whose address is registered at the College.

The Services.

DEATHS IN THE SERVICES.

Colonel William George Beyts, C.B.E., Army Medical Service (ret.), died in Queen Alexandra's Military Hospital, Millbank, on February 12th, aged 63. He was born on February 24th, 1865, educated at Guy's, took the M.R.C.S. and L.R.C.P.Lond. in 1889, and entered the army as surgeon lieutenant on January 30th, 1892. He attained the rank of lieutenant-colonel on January 1st, 1914, got a brevet colonelcy on January 1st, 1917, became colonel on December 26th, 1917, and retired in 1924. After retirement he filled the post of medical officer of the Tower of London. He served on the north-west frontier of India in the campaign of 1897–98, with the Kohat and Kurram Valley forces, took part in the action of the Ublan Pass, was mentioned in dispatches in the *London Gazette* of December 21st, 1897, and gained the Frontier medal with two clasps; also in the South African war in 1902, receiving the Queen's medal with three clasps.

Lieut.-Colonel Alexander John Willcocks, Bengal Medical Service (ret.), died of pneumonia at Dehra Dun on January 14th, aged 77. He was born on May 15th, 1851, the son of the late Captain W. Willcocks of the Indian Army, and was educated at Aberdeen, where he graduated as M.B. and C.M. in 1873, and as M.D. in 1883, and at Guy's, also taking the M.R.C.S. in 1873. He entered the I.M.S. as surgeon on September 30th, 1873, passing in first, of the first batch admitted to the service after the abolition of the rank of assistant surgeon, became lieutenant-colonel after twenty years' service, and retired on April 1st, 1901. For two years, 1903–5, he acted as a member of the India Office Medical Board. He rejoined for service in the war of 1914–18, when he served in Egypt, and was mentioned in dispatches in the *London Gazette* of July 6th, 1917. After the war he settled in India. Nearly the whole of his service was spent in civil employ in the North-West Province, now the United Provinces. While serving as civil surgeon of Bulandshahr, a small and unimportant station in that province, he distinguished himself by performing a greater number of surgical operations than had ever been done by any civil surgeon before, especially extractions of cataracts. Others may have met with even greater success in this direction in later years, but it was Willcocks who first

discovered the great field for surgical work, especially on the eye, which an Indian district affords, and originated the great development of surgery in India which started in the early eighties of last century. He was one of four brothers who all achieved considerable success in life, and, indeed, might be compared, on a smaller scale, to the Malcolms and the Lawrences. The eldest brother was a chaplain on the Indian Ecclesiastical Establishment, A. J. Willcocks was the second. Sir William Willcocks, K.C.M.G., the famous Egyptian engineer and head of the Irrigation Department in Egypt, was the third, and the youngest was General Sir James Willcocks, K.C.B., who commanded the Indian troops in France in 1914.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Local Government Bill was read a third time by the House of Commons on February 18th and sent to the House of Lords, where it was formally read a first time on February 19th. The second reading and committee stages were to follow quickly. Days of the committee stage of the Local Government (Scotland) Bill were set down in the House of Commons on February 20th, 21st, and 22nd.

In the House of Lords, on February 19th, a bill to render void marriages between persons either of whom is under the age of 16 was read a second time.

A meeting of the Parliamentary Medical Committee has been summoned for February 26th.

Local Government Bill.

Report Stage.

The House of Commons, on February 12th, began consideration of the Local Government Bill, as amended in committee, on the report stage.

On Clause 4, which deals with administrative schemes, Mr. WITHERS moved an amendment providing that a county council, in the preparation of any scheme relating to hospitals, should consult with the representatives of the voluntary hospitals in the area, with a view to co-operation in the treatment of the sick and the avoidance of overlapping. He said he desired that there should be consultation between the public assistance committees when formed and the voluntary hospitals, and that provision should be made for the most efficient service for the sick when the scheme came into operation. The voluntary hospitals had a very high standard of efficiency in their technical work, and there was an admirable spirit behind that work. When the county councils took over the local infirmaries it was very important that there should be co-operation between what would be the county council hospitals and the voluntary hospitals, because otherwise there would be overlapping, and trouble would arise. It must be disastrous to the voluntary hospitals if the impression was given that these two classes of hospitals were in competition. It was very important that they should work together in harmony, and that it should be understood that the one was not going to supersede the other. Major GLYN seconded the amendment.

Mr. CHAMBERLAIN said that any county council, in preparing a scheme, must have regard to the voluntary hospital provision already existing in that area. It was obvious that no scheme which proposed to deal with the hospital services of the area could really be adequate unless it took account of the existing accommodation in the voluntary hospitals. He was in full sympathy with the general idea of Mr. Withers—that there should be consultation and co-operation between the two classes of hospitals; but he did not think it would be possible to insert this particular amendment. If they were to provide for consultation with representatives of the voluntary hospitals, logically, they could not stop there. There were other voluntary associations doing work on parallel lines with some of the work which it would be the duty of the county councils to perform, and if they were to consult with the representatives of the voluntary hospitals it would only be logical to say that they must consult also with representatives of those other associations. Another practical difficulty was that neither the voluntary hospitals nor those other bodies were organized. There was no system by which they could, as a body, consult with the county council, and to make that a statutory provision would be a mistake. His view was that consultation and co-operation would take place between the voluntary hospitals and the public authorities, but it would not be acceptable to the local authorities if Parliament were to try to lay down precisely how that consultation and co-operation should be carried out.

Major GLYN said that in rural areas a very large number of workers had long been contributing each week to the voluntary hospitals, and it would be hard upon them if the scheme did not take into account the enormous amount of work which had been done in consequence of their contributions. Those interested in hospital work felt that some organization—even if it had to be created *ad hoc*—ought to be taken into consultation in connexion with this scheme.

Mr. W. BENN, in supporting the amendment, pointed out that under the Safeguarding Provisions the Government taxed drugs for hospitals. Two days ago a document was published saying that the assessments of hospitals were actually being raised. Sir R. SANDERS said that on almost every county council there was someone who represented the voluntary hospitals and looked after their interests. Colonel GRETTON, as one who had a great deal to do with the administration of two local hospitals, urged Mr. Chamberlain to accept the amendment. The large hospitals in the country no less than those in the metropolis ought to be taken into consultation in these matters, because they were schools of medicine; they were the ground where the medical profession received its training, and they would not be superseded by the system which the Minister had set up. Mr. HARRIS said that the London County Council had already considered this problem so far as London was concerned, and their way was comparatively easy. They had the King Edward Hospital Fund in London, and had an immense opportunity of making something like a perfect hospital system for the metropolitan area.

The amendment was negatived without a division and the clause agreed to.

Mr. PETHICK-LAWRENCE moved to omit Clause 15, which deals with the recovery of expenses. He said that the clause was inimical to public health. It compelled local authorities to make a charge on all persons using their health institutions, with certain exceptions, and it fixed the amount which the authorities must charge. He had made inquiries, and he estimated that in London that charge would reach from £2 5s. to £2 10s. a week in the case of maternity homes, and from £4 5s. to £4 10s. a week in the case of cancer hospitals. Further, the clause provided that if a patient could not pay, all the persons on whom the patient was regarded as dependent could be called upon to pay the whole of the charge. That would debar members of the working classes from making use of these hospitals. The Minister of Health had put down an amendment which would enable local authorities to refrain from charging the full bill, not only when they were satisfied that the patient or his relatives could not pay, but when they thought it unreasonable that they should pay. That was a very considerable advance, but there remained a great deal of ground where the clause would still fail to meet criticism.

Sir KINGSLEY WOOD said that no one could describe the clause as detrimental to public health. If the clause were deleted the local authorities to whom the institutions were being transferred from the guardians would be under the obligation to charge a pauper for treatment while they would have no such duty in the case of a person who did not come under the operation of the Poor Law. The clause assimilated the position, so that in all cases, except those of infectious disease, where a person could afford to do so, having regard to his financial circumstances, he should make a reasonable payment to the local authority for the treatment he received.

Dr. VERNON DAVIES said that, as a medical man, he hoped he would live long enough to see the treatment of disease according to need and not according to the financial capacity of the patient, and to see the break-up of the Poor Law. They had been assured by the Minister that at present the time for that was not ripe; that it would be impossible for the bill to function and at the same time to break up the Poor Law. So they had the position that under the Poor Law the destitute poor or their relatives could be charged by the local authority a certain amount for their treatment and maintenance, and that, on the other hand, the people who were not poor who were treated under the Public Health Act could escape free. That was a very alarming position, and was undoubtedly penalizing the pauper. They would all have liked to get rid of the pauper charge if they could, but not being able to do that, and as it was not possible even to put all sickness for the time being on the same level, the Minister was making a charge for everybody according to their means. There was to be no increase of the present charge according to the Poor Law. They were not raising the Poor Law fees, nor altering the Poor Law structure. They were to go on as they had been going on for many years. He had had several years' experience in an industrial practice, and he had known of many instances where patients had to go to voluntary hospitals, and also to the Poor Law hospitals. He could say with confidence that never in the whole of his experience had he come across a case where any complaint had been made by patients or relatives of undue charges for hospital attendance, either in the Poor Law hospitals or the voluntary hospitals. The circumstances of the patient were taken into account, the circumstances of the relatives were taken into account, and his experience had been that the people, when they had come out, had been very grateful for what had been done to them. They were not going to alter that by the bill. They were simply going to put them all on the same level until the happy time arrived when they could remove the Poor Law disqualification for illness. Members of the Labour party were perhaps unduly apprehensive of the dangers of this clause. They seemed to think that people would be afraid to go

to the hospitals on account of the charge. When people were ill money did not count. Treatment came first, and they went to the hospitals and were only too glad to get there. He could not understand why the Labour party should have the idea that the Government, the hospital authorities, and the guardians of the poor were simply out to rob the poor of all they could. (Labour cries of "No.") The suggestion was that the charge they were going to make, legally or illegally, was so high that the people would be terrified to go into hospitals on account of that charge. It had been said that people with cancer, rather than go to these hospitals and pay an enormous price, would sit at home and run the risk of suffering, and would rather die for lack of treatment. That did not happen. He had never heard a case of any patient, pauper or otherwise, suffering from a disease like cancer where the patient did not get the best medical attention and where everything was not done that could be done to give him relief. The bill was altering the law, but it was doing nothing to increase the standard which at present existed under the Poor Law. It had been said that unless a person could pay £3, £4, £5, or £6 they could not go in, but that did not happen. The clause was of great benefit to the bill. The ordinary working folk wished to be treated no better than were the paupers.

The amendment was rejected by 221 votes to 114, and the amendment of the Minister of Health, referred to in Mr. Pethick-Lawrence's speech was inserted. The clause was then agreed to.

On February 13th Mr. CHAMBERLAIN carried an amendment extending to the county of London the clause empowering county councils to act jointly with other local authorities in preparing or adopting town-planning schemes.

Clause 54 authorizes the Minister to make regulations regarding the qualifications of medical officers or health visitors appointed by a local authority under the Maternity and Child Welfare Act, 1918, and the Public Health (Tuberculosis) Act, 1921, or under any regulations for the treatment of venereal disease made under the Public Health Acts. On the motion of Mr. CHAMBERLAIN the House added, after "Public Health Acts," the words "1875 to 1925, and the Public Health (London) Act, 1891."

Clauses 55 on maternity and child welfare services, 56 on notification of births, and 57 on supervision of midwives, were all carried without debate. Clause 58 provides for the survey, by county councils, of the hospital accommodation provided for the treatment of infectious disease, and for the submission to the Minister of schemes for providing adequate hospital accommodation for such disease. Mr. CHAMBERLAIN moved and carried an amendment declaring that in this clause "infectious disease" should not be construed as including tuberculosis or venereal disease. He said these were already separately covered.

Clause 94 empowers the Minister to reduce grants to councils which have failed to achieve or maintain reasonable progress in public health services. On the motion of Sir KINGSLEY WOOD this was amplified to make clear that the Minister could thus act either on representations made to him by any association or body of persons experienced or interested in matters relating to public health, or without such representation. Sir Kingsley Wood said the amendment had been pressed from all quarters of the House.

Clause 120—"power to remove difficulties"—was discussed on February 14th. Mr. PETHICK-LAWRENCE asked if the Minister's power to modify certain provisions would apply to the definitions clause. That clause did not define infectious disease. It might be convenient for the Minister, "for the purpose of removing difficulties," to say that no kind of tuberculosis should be included in the definition of infectious disease.

Sir KINGSLEY WOOD said that if a local authority wished to find out what an infectious disease was it must look elsewhere than in this bill.

On Clause 123, which sets out definitions, Dr. FREMANTLE moved to insert the following definition of infectious disease:

"'Infectious disease' means any of the diseases named in the Infectious Diseases (Notification) Act, 1889, Section 6, and any other diseases added thereto by order of the local authority with the approval or concurrence of the Minister of Health, or any infectious disease made notifiable by Order of the Minister of Health under Section 30 of the Public Health Act, 1875, and the corresponding Section of the Public Health (London) Act, 1891."

Dr. Fremantle said that Clause 15 of the bill contained no definition of infectious disease, though it made an exception concerning the recovery of a contribution towards the cost of treatment from a person suffering from such disease. For administrative purposes a uniform definition of these excepted diseases was necessary. The definition might be "diseases which are notifiable by law." It was absurd to leave infectious disease to be defined by any medical man.

Mr. CHAMBERLAIN said he could not accept the amendment. The definition suggested by Dr. Fremantle would exclude venereal diseases, which were not notifiable. Infectious diseases were not defined in the Public Health Acts, and therefore not in this bill.

The amendment was negatived, and after further debate the report stage closed.

Third Reading.

The Local Government Bill was read a third time by 292 to 113 on February 18th. In moving the third reading Mr. CHAMBERLAIN said the measure was not going to stifle or cripple local services, but would prove a jumping-off ground for a fresh leap forward of the standard of health and welfare throughout the country. He defended the financial basis of the bill.

Mr. ARTHUR GREENWOOD, on behalf of the Labour party, moved the rejection of the bill, one reason adduced in the motion for rejection being that it would degrade the standard of the social services and cripple their development.

Mr. PETHICK-LAWRENCE, seconding, said the bill could not be practical when it gave relief to breweries and none to hospitals.

Mr. ERNEST BROWN condemned the bill for concentrating health services in the hands of county councils and county boroughs, and for dissipating the funds that would make the health services effective. He predicted that the block grant would prove insufficient all over the country. At present there were 350 whole-time medical officers of health and 1,150 part-time officers. He anticipated that in five years those figures would be reversed, that every one of these doctors would want assistants, and that, if they were to do their job, the money provided by the block grant would not suffice. The bill had gone too far in the centralization of health services.

Dr. FREMANTLE desired to sum up the bill's use and value to the public health and local government services. The bill was a definite help to agriculture, and agriculture was of value from the health point of view as the basis of country life. The Poor Law, which the bill sought to change, was the first main provision made by Parliament for protection of the health of the people. Out of its institutional and outdoor relief was developed the system of medical attendance free for every man, woman, and child. He regretted that, as time became ripe for another development of local government, the House, instead of founding health services on the Poor Law, set up another system under urban and district councils. In 1883 Parliament further established the county councils, and as a result public health for forty years had had a multitude of authorities and a tangle of administration, which had meant inefficiency, weakness of resources, and dissipation of attention and energy. Medical officers trying to carry out health measures realized the enormous resources of the Poor Law. The bill's proposals for consolidation were not a final solution, but were going in the right direction by placing Poor Law into the hands of the county councils and by co-ordinating the work of the county councils with local sanitary authorities. He attached importance to the powers given in the bill for the overhauling and systematizing of schemes for infectious diseases, water supply, and sewage disposal. On some points those who were interested in such matters were not entirely satisfied, but they were minor points, and he hoped amendments might be made on them in the House of Lords.

Mr. GATES said he had criticized the bill because he feared maternity and child welfare services would suffer under the block grant system. A great many of the voluntary associations were still not quite easy in their minds, but they were a great deal easier since certain amendments had been inserted in the bill by the Government. The voluntary associations, which had done so much work in connexion with public health services, would have much preferred that the maternity and child welfare services should still have been left on the percentage grant system for the original term of seven years if that had been possible. The voluntary associations could not help being afraid that many councils would prefer to use the block grants for the purpose of reducing their rates rather than for promoting these services. It was an unfounded fear, and the Government's amendments would reduce the grounds for it to a minimum.

Sir KINGSLEY WOOD said that one of the most unfounded criticisms of the bill was that which found a place in the Labour party amendment—namely, that the proposals of the bill would degrade the standard of social service in the country. The discussion on block *versus* percentage grants had amply demonstrated that there was hardly anyone who was prepared to stand up wholly for the present percentage grant system. A most welcome fact had been the considerable change of opinion among people particularly interested in the maternity and child welfare service proposals of the bill. It had been more and more appreciated that the present system benefited the rich areas and handicapped the poor areas, and that there was no effective power vested in the Minister of Health to bring about a better state of things in the case of an authority that was not properly discharging its health duties and functions. The debates on this bill had clearly demonstrated that the new system would at any rate remedy many of those grave defects.

The Labour amendment to reject the bill was defeated by 292 votes to 113, and the bill was then read the third time.

The bill was introduced into the House of Lords on February 19th and read a first time.

The Assessment of Hospitals.

In an answer given on February 13th to Sir Nicholas Grattan-Doyle Sir KINGSLEY WOOD said hospitals could not be exempted from rating without legislation. Mr. Chamberlain was of opinion that such a proposal could not be considered apart from the claims made for other charitable and public institutions. The

same considerations applied to preferential terms of assessment. The Government desired to do what it could for voluntary hospitals, but if they began to give preferential treatment they would be confronted with claims on behalf of blind institutions and other institutions. The Central Valuation Committee had made recommendations with respect to the assessment of hospitals and charitable institutions, and when these recommendations had been adopted there should be no undue hardship.

On February 14th Mr. ROBERT MORRISON put a question asserting that under the Rating and Valuation Act, 1925, the assessment of provincial hospitals in England and Wales had been increased from £1.56 per patient bed to £2.36 per patient bed. Mr. CHAMBERLAIN replied that he had no general information on the effect of the revaluation of hospitals. The subject would probably be discussed many times, but in legislation this Parliament had said its last word. In Sheffield the new assessments of all the voluntary hospitals showed an increase of £11.

Automatic Machines for the Sale of Aspirin.—Sir ROBERT THOMAS asked, on February 13th, whether Mr. Chamberlain was aware of a proposal to install automatic machines for the sale of aspirin, and whether the uncontrolled sale of this drug was in the public interest. Sir KINGSLEY WOOD said the question had been referred to the Inter-Departmental Committee on the Poisons and Pharmacy Acts, whose report Mr. Chamberlain must await. He could not say when that report would be received.

Central Midwives Board and Instruction of Pupil Midwives.—On February 14th Mr. CHAMBERLAIN, answering Mr. P. J. Hannon, said he knew the Central Midwives Board had directed that pupil midwives at the two hospitals of the Birmingham guardians should cease to take their theoretical instruction within these hospitals. In this matter he had no authority to interfere with the discretion of the Central Midwives Board. A departmental committee was considering the powers of the board, and a question like that from Birmingham would come within the terms of reference. Mr. Chamberlain returned a similar answer to Sir Philip Richardson, who called attention to the fact that the Central Midwives Board had instructed the Kingston-on-Thames board of guardians that pupil midwives were not to receive lectures from the medical superintendent of the Kingston and District Hospital.

Notes in Brief.

During the twelve months ended February 1st Mr. Chamberlain confirmed schemes for clearance of insanitary areas in Chelsea, Leeds, Sheffield, Knaresborough, Wednesbury, Brampton, Preston, Rochdale, Exeter, and Liverpool. Nine schemes are at present under his consideration.

During 1928 eighteen airmen were discharged from the R.A.F. suffering from pulmonary tuberculosis. Three of these cases were held to be attributable to service. The number of men discharged from the army for tuberculosis in 1928 is not yet available.

The Home Secretary states that to remove injured persons to hospital the Metropolitan Police make use of the ambulances of sixty different agencies, including the St. John Ambulance Association, forty-two urban district councils, and thirteen borough councils.

It is not the practice for Poor Law inspectors of the Ministry of Health to attend inquests on persons dying in Poor Law institutions.

Under the direction of the First Commissioner of Works a survey of places in London available as shelters from aerial attack is being made.

Medical News.

AT a meeting of the Royal Society on February 28th, at 4.30 p.m., a discussion on ultramicroscopic viruses infecting animals and plants will be opened by Sir Charles Martin, F.R.S.

UNDER the auspices of the National Council for Mental Hygiene Dr. W. A. Potts will deliver a lecture on "The irresistible impulse" at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Wednesday, February 27th, at 5 p.m.

THE Sections of Urology, Pathology, and Therapeutics of the Royal Society of Medicine will hold a joint discussion on urinary antiseptics on Thursday, March 21st, at 8.30 p.m.

IN connexion with the inauguration of the Jordanburn Nerve Hospital, the chairman and managers of the Royal Edinburgh Hospital for Mental and Nervous Disorders have issued invitations to a dinner in the Hall of the Royal College of Physicians of Edinburgh on Monday, February 25th.

DR. HECTOR CAMERON will lecture for the Fellowship of Medicine on Monday, February 25th, on "Appendicitis and other causes of acute abdominal pain in children" at the Medical Society, Cavendish Square, W.1, at 5 p.m. On Wednesday, February 27th, at 4 p.m., a clinical demonstration will be given by Dr. Knyvett Gordon on "The leukaemias and Hodgkin's disease" at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1. On the same day and at the same time Dr. Kenneth Playfair will demonstrate heart cases at the Royal Waterloo Hospital. The lecture and both demonstrations are free to medical practitioners. A week's intensive course begins at the Brompton Hospital for Chest Diseases on February 25th. The Hospital for Sick Children will provide a morning course from February 25th to March 9th; early application is desirable as the class is limited to 20. In March two special courses only will be held, both of these from March 11th to March 23rd. The first is an all-day course at the Royal National Orthopaedic Hospital, the minimum entry being 10. The second is in ophthalmology at the Royal Eye Hospital, and consists of instruction in the afternoons only. Copies of all syllabuses, specimen copies of the *Post-Graduate Medical Journal*, and information relating to the general course, consisting of the clinical practice of the various affiliated hospitals, can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

DR. R. G. CANTI of London and Dr. Regaud of Paris, who recently delivered addresses at the Berlin Medical Society on the control of cancer, have been elected foreign members of the German central committee for the investigation and control of cancer.

AMONG the various special holiday tours arranged for members of the medical profession one of the most attractive is the annual cruise organized by the *Bruxelles-Médical*. This year the cruise will extend over twenty-four days, from July 13th to August 4th, passengers embarking and leaving the motorship *Brazza* at Zeebrugge. From Zeebrugge the *Brazza* will cross the North Sea to Kopervick, and the following eight days will be spent in cruising round the fiord-broken coast of Norway, with opportunities for visits to places of interest. The voyage will then be continued north into the polar circle to Svartison and the Lofoden Isles, the return journey being broken by calls at the Faroe Isles, the Shetlands, and at Leith. The fares, not including excursions, will range from £20 5s., in the second class, up to £92 5s. 6d., de luxe, per person for doctors and their relatives. Persons not connected with the medical profession but vouched for by their family doctor may be admitted to the cruise at slightly higher rates. Early application for particulars should be addressed to Croisière "Bruxelles-Médical," 29, Boulevard Adolphe Max, Brussels.

THE Ministry of Health has issued a memorandum (No. 139) describing the bacteriological standards for the various classes of graded milk prescribed by the Milk (Special Designations) Order, 1923, the methods of sampling milk, the laboratory technique of bacteriological examination, and the form in which the results of examination should be recorded. The leaflet may be obtained from His Majesty's Stationery Office.

DR. G. B. HILLMAN has been appointed a Justice of the Peace for the county borough of Wakefield.

AN alabaster tablet in memory of the late Professor E. M. Crookshank, M.B., has been placed in East Grinstead parish church.

THE Meteorological Office has issued Section VI of the *Book of Normals* of meteorological elements for the British Isles, containing normals of relative humidity. This publication includes an explanatory chapter containing a note on relative humidity and a description of the methods used in securing the data for the tables and isopleth diagrams which follow. These contain the normals of relative humidity for each hour of the day in each month and in the year for twelve observatories in the British Isles. Copies of the pamphlet may be obtained from H.M. Stationery Office, or through any bookseller, price 9d. net.

A RESIDENTIAL school for children, aged from 4 to 10, and crippled by surgical tuberculosis, infantile paralysis, or rickets, has been established at Bournemouth by the Shaftesbury Society and Ragged School Union. There is a similar institution at Hastings for boys aged 10 to 16, and another at Margate for girls in the same age group. The schools have been approved by the Ministry of Health and the Board of Education as centres to supplement the provision made in hospitals and schools for the physically defective. Further information will be supplied by the secretary of the society, John Kirk House, 32, John Street, W.C.1.

THE Hungarian Minister for Public Welfare and Labour has convened a conference on *x*-ray and high current prophylaxis, under the chairmanship of the State Secretary, Dr. T. de György. A committee of *x*-ray experts and engineers was appointed subsequently to draw up a scheme of prophylactic rules against *x*-ray and high current injuries; to watch the scientific and technical development of radiology; and to keep in touch with foreign committees of this kind. Its first meeting was held in Budapest on February 4th.

WE have received a copy of a little work on Sweden issued as a souvenir of the Swedish section of the International Press Exhibition held last year at Cologne. In addition to miscellaneous information about the country the work contains an interesting and lavishly illustrated account of

the Swedish press from the earliest times until the present day, and an attractive article on Sweden as a country for tourists, from which we learn that a free supply of drinking water changed several times daily is provided in all the railway carriages, an example which might be followed in other countries.

THE National Baby Week Council has awarded the Lady Astor shield to the Kettering Urban District Council Ladies' Voluntary Committee for Infant Welfare for the most effective local Baby Week campaign in a large area in 1928. The Oldbury Infant Welfare Centre secured the second place and will receive a special trophy. Certificates of merit have been gained by the Bilston Urban District Council, Kingston-on-Thames Infant Welfare Centre, and Sunderland County Borough. The William Hardy Shield, which is reserved for smaller areas, was won in 1928 by the Hill and Cakemore (Worcestershire) Infant Welfare Centre, the Halesowen Centre securing second place. Certificates of merit were awarded to Bungay (Suffolk) Nursing Association, East and West Molesey (Surrey) Infant Welfare Centre, Lymington (Hants) Infant Welfare Centre, and Welwyn Garden City (Herts) Health Association.

THE British Engineering Standards Association, which represents all the principal engineering institutions, has issued a British standard specification for the electrical performance of transformers for *x*-ray purposes. It is the first specification of the kind to be issued relating to *x*-ray apparatus, and it applies to the main high-tension transformers, dealing with the subject on lines similar to the corresponding specification for the electrical performance of transformers for power and lighting, but with the necessary modifications to meet the service conditions of *x*-ray work. The definition of the rating of the transformer is given, also the method of testing output, and some notes on rectification. Copies of the specification (No. 326, 1928) can be obtained at 2s. 2d., post free, from the Standards Association, 28, Victoria Street, London, S.W.1.

WE have received the report of the School of Medicine of Shantung Christian University which covers the year ending August 31st, 1928. This University which is under joint British and American control, suffered severely from the recent disturbed conditions in China; the diploma of the medical school was, however, awarded to twenty students last May. It is hoped that during the present year more settled conditions will prevail and enable the University teaching to be extended.

THE most recent issue of the sections of the International Labour Office *Encyclopaedia of Industrial Hygiene* contains Brochures No. 134 and No. 140, dealing with basic slag, basket weaving, bones industry, boot and shoe manufacture, brass, brooms, and building trades respectively. This issue completes the subjects coming under the letter "B," which may therefore now be assembled in their correct order. When the pamphlet edition is complete the entire work will also be issued in volume form.

A LIST of students from other countries who are studying in the universities and university colleges of Great Britain and Ireland in the current session has been published, at the price of 1s., by the Universities Bureau of the British Empire, 50, Russell Square, W.C.1. The list includes 5,170 names—against 4,875 a year ago—arranged according to their countries under each university or college. Each continent and practically every European country—from Turkey to Iceland—is represented; there are over 1,500 names of students from India, and between 500 and 600 in each case from the United States and South Africa. At the other end of the scale Armenia, Manchuria, and the Dutch East Indies are each represented by one student.

WITH a view to disseminating information about the proceedings of Hungarian medical societies and publications, arrangements have been made to publish, at fortnightly intervals in German, a journal of clinical abstracts and medical news entitled *Verhandlungen der Ungarischen Aerztlichen Gesellschaften*. It may be obtained from the editorial office, Vadász-utca 26, Budapest V, the annual subscription being £1.

THE Rumanian Government has conferred the distinctions of Grand Officer of the Crown of Rumania on Professor Marcel Labbé, and of Commander of the Star of Rumania on Professor Rathery, Dr. Laignel-Lavastine, and Dr. Armand-Delille on the occasion of the fifth congress of thalassotherapy.

THE following appointments have recently been made in foreign medical faculties: Dr. Eckert Möbius, professor of oto-rhino-laryngology at Halle, in succession to Professor Denker; Dr. Tarozzi, professor of morbid anatomy; Dr. Centani, professor of general pathology at Bologna; and Dr. Reeb, professor of gynaecology and obstetrics at Strasbourg in succession to the late Professor Schickelé.

A PAN-PACIFIC congress of surgery will be held at Honolulu in April.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863*, and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocrity Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF NAEVUS IN INFANTS.

"FREE STATE" asks for advice how to treat a child 6 weeks old who has a naevus on the cheek about the size of a threepenny piece. It was not noticed till the child was about ten days old. Ought operation to be postponed till the child is older; and what operation would be best—the electric needle, caustic, ligature, or the knife?

DRY SKIN.

DR. E. MARGARET PHILLIPS (Pekin) writes: In reply to "H. M. C.'s" query on December 15th, 1928 (p. 1120), I would suggest simple lanolin for his patient's skin cracks. The Pekin climate is very dry, and numerous cracks on the finger-tips and sides used to make the winters miserable for me, but since I discarded all creams and lotions at the beginning of this winter and used only Messrs. Burroughs Wellcome and Co.'s toilet lanolin I have not had a single crack. My hospital patients are quite happy with plain vaseline or boric ointment, but I like this lanolin because it does not leave the skin greasy. I apply it two or three times a day, and wash the hands in cold water during the daytime.

SOUND-PROOF DOORS.

DR. F. G. GARDNER (Oxford), in reply to the question on February 16th (p. 331), how to prevent the transmission of sounds between consulting and waiting rooms, writes: "Inquirer" will probably find much to interest him in an article in the *Times* of February 5th, entitled "Quietness in City offices." This article, which deals with the application of [illegible] as a special seaweed from Nova Scotia, [illegible]itten in such convincing style that it noise abatement, in so far as it applies or part thereof, is almost settled.

INCOME TAX.

Replacement of Car.

"A. B." bought an 11.9-h.p. car, two-seater, in 1922 for £490, and has sold it for £30, buying a 15.9-h.p. saloon for £375. What can he deduct for income tax?

*** The principle involved is that no expenditure in respect of improvements can be deducted. Horse-power is an element, but only one among several, in that question. Prima facie, however, the new car is one of a better range or type than the 1922 car, and, if so, the amount allowable is, strictly, the excess of the cost in 1928 of a car similar to the one replaced over the £30 received.

Car Transactions.

"R. S. T." has hitherto adopted the basis of renewals, his last allowance being made in respect of a renewal occurring in 1927. He contemplates retiring in 1930, and inquires whether he should now change the basis of allowance.

*** Yes; otherwise, of course, he will never receive any allowance for the car he is now using. He could *not* have changed for 1928-29 because the 1927 allowance is, in effect, made for that year, inasmuch as he is assessed on the previous year's basis. Consequently, it seems that he will receive an allowance for 1929-30 only.

Expenses while on Colonial Leave.

"S. W. T. L.," a medical officer in the Colonial Service, is home on leave. Can he deduct anything in respect of expenses incurred (*a*) in the purchase and future freight to the colony of a car which is being used for pleasure but will be taken abroad for professional use, and (*b*) in connexion with a post-graduate course he is taking?

*** (*a*) Present expenses are not wholly, exclusively, and necessarily incurred in the performance of the duties of his office and cannot be deducted in the taxation of his leave pay. (*b*) No; such expense is analogous to capital outlay for a future return.

Colonial Gratuities.

"J. C. D." asks if gratuities for services in military and colonial medical services are subject to income tax, whether the recipient is a British resident or not.

*** Gratuities paid in respect of service in connexion with the Great War to members of the military forces of the Crown were specifically exempted by Section 17 of the Finance Act, 1919. If our correspondent's gratuities do not fall within that description, we do not know of any grounds on which they can be claimed to be outside the scope of the tax. Non-residence in the United Kingdom, however, would seem to be sufficient, provided that no remittances are made to this country out of the gratuities.

Cash Basis: Retirement from Practice.

"T. T." retired on April 1st, 1928, his partner taking over the whole of the practice, but not "T. T.'s" share of the book debts. Is "T. T." liable on the subsequent cash receipts.

*** No. So far as our correspondent is concerned, these receipts represent the realization in cash of the results of past earnings. From April, 1928, onwards the remaining partner is liable in respect of the whole of the profits of the practice. If those profits are measured on the basis of the value of bookings after April 1st, 1928, no complication arises; if on the cash receipts basis, then it is clear that the whole of the receipts, including "T. T.'s" share, must be reckoned in the computation, otherwise the "receipts" will not correctly indicate the full practice profits.

LETTERS, NOTES, ETC.

THE MAYOS.

WE wish to correct an error which crept into the annotation published under the above heading in our last issue (p. 309). In column 2 it is stated that William Worrell Mayo received his medical education in Manchester. This is not correct. He was a pupil of John Dalton, the famous chemist, and after he went to New York in 1845 he practised as an analytical chemist. He did not take up a medical career until later, obtaining his medical degree from the University of Missouri in 1854. To quote the *Manchester Guardian* of February 2nd, he became a pioneer, not only in surgery, but in the establishment of civilized life.

TREATMENT OF INFLUENZA.

DR. J. T. MACLACHLAN (Ardrossan) writes: I regard influenza as the most curable of all the acute diseases which a practitioner is called upon to treat. By influenza I mean a disease with a rapid onset, a smart rise of temperature being associated with a severe headache and pains all over the body in the muscles (myositis). The back muscles are very tender, particularly below the right scapula. The drug I have used for over twenty years is sodium salicylate, given in doses of 20 grains every two hours. About 120 grains are all that an adult man will require. All pains should then have gone and the temperature have returned to normal. Profuse sweating is the rule after taking the drug. For women 15-grain doses will suffice. If influenza is not promptly brought to an end with six doses, then we are probably dealing with a case of pneumonia, over the course of which the drug is useless.

THE HEREDITY OF DEMENTIA PRAECOX.

DR. J. E. DHUNJIBHOY (Medical Superintendent, Ranchi Indian Mental Hospital, Bihar and Orissa, India), in the course of a letter on this subject, writes: I entirely disagree with the opinion expressed by Lieut.-Colonel Jagoe Shaw (*British Medical Journal*, September 29th, 1928, p. 566) that "inbreeding" is a very definite cause of the high incidence of dementia praecox among the Parsees of India. The incidence of this disease is high in England, Germany, France, Italy, and America, yet none of these nations is known to practise inbreeding like the Parsees. Parsees are the most Europeanized community of India and they follow Western civilization, especially on its educative side. In my own experience of lunacy work in India I have found that the incidence of dementia praecox is always high among the educated classes; it is high among the educated class of Bengalis, who, like the Parsees, follow Western civilization and education; for similar reasons it is high among the domiciled Anglo-Indians. I am entirely with those who believe that the stresses of present-day civilization and education, though not the sole cause of dementia praecox, at least have something to do with it. I am in no sense a champion of inbreeding, and fully realize its undesirability, but what I am urging is that its relationship to dementia praecox has never been definitely established. The Parsee community has been inbreeding for more than 1,200 years, and its general health is not impaired as compared with that of other communities of India which do not practise inbreeding. Further, as the general consensus of opinion is in favour of greater hereditary predisposition in manic-depressive psychoses than in dementia praecox, inbreeding should produce more manic-depressive psychoses among Parsees than dementia praecox. Yet these psychoses and other organic inherited diseases which inbreeding is bound to influence are not increasing among the Parsees. Finally, figures taken from the annual reports of the various provincial mental hospitals in India should convince Colonel Jagoe Shaw that dementia praecox is not so rare as he imagines amongst other communities in India.

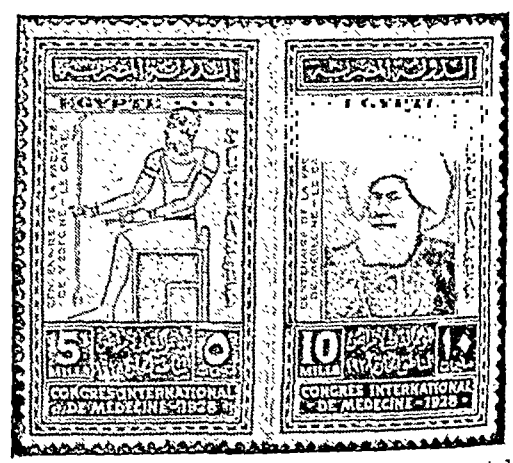
HYDROCEPHALUS WITH BREECH PRESENTATION.

DR. K. R. KINI (Mangalore, India) writes: In view of its rarity the following case of breech presentation deserves recording. A primipara, aged 18, after labour for three days, gave birth to a child as far as the neck, when progress ceased, though the pains continued. A country midwife had tried embryotomy, cutting open the spinal canal and exposing the structures of the neck; a meningocele in the lumbar region had been opened. The diagnosis lay between twins and hydrocephalus. Vaginal examination revealed the face of the child posteriorly, the occiput anteriorly; no other foetal parts could be felt, so I decided it must be a case of hydrocephaly. I tried perforation of the head through the mouth, but could not succeed; next I tried through the exposed spinal column, but failed again; then I rotated the head, bringing the occiput posteriorly, and perforated with success, evacuating four pints of clear straw-coloured fluid. The uterus began to act with great force, and the cranium was delivered without further delay, as was also the placenta. On the second day there was a temperature of 99° in the morning and 101° in the evening, but by the fourth day it was normal, both morning and evening, and the discharge was healthy. By the ninth day the patient was taking normal diet and had recovered from her uterine trouble, but on the tenth day she had an attack of pneumonia and died three days later. I wish to draw attention to the fact that it is not possible in such a case to perforate through the mouth; it is necessary to get the head posteriorly and perforate.

INTERNATIONAL MEDICAL CONGRESS AT CAIRO.

Commemorative Stamps.

DR. JAMIESON B. HURRY (Bournemouth) writes: In honour of the International Medical Congress recently held at Cairo, the Egyptian Government has issued two postage stamps which possess some historical interest. The first stamp (5 millièmes)



depicts Imhotep, the Egyptian Deity of Medicine, seated on his throne, grasping the sceptre of power in his right hand and the "ankh," or symbol of life, in his left. The second stamp (10 millièmes) exhibits a portrait of the Viceroy Mohamed Aly Pasha, to whom the foundation of the Medical School of Cairo one hundred years ago was due. This is probably the first time in the history of medicine that one of its tutelary deities has appeared on a stamp.

ASTHMA IN CHILDREN: A CORRECTION.

WE are asked to make the following correction in the article by Drs. R. H. Simpson and K. Stone published in the *Journal* of February 16th (p. 291), the corrected proof of which was not received until after we had gone to press. The last sentence in the small type paragraph immediately preceding the final paragraph of the article (p. 293) should read: "Cases 1, 3, and 9 are improved, but to a lesser degree than the four cases mentioned above." In the following line (*the fourth from the end*) for "six" read "four."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 51.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

180. Calculous Pleurisy with Serous Exudate.

C. GENTZ (*Acta Med. Scand.*, December 28th, 1928, p. 399) agrees with the majority of authors that it is not unusual to find in old pleuritic adhesions patches of calcification, especially in the parietal pleura. These patches consist usually of dense calcified fibrous tissue, often presenting the appearance of bony plaques ("pleural bones"), but actual ossification is rare. One writer states that these calcifications usually follow tuberculous empyema, but they often occur after non-tuberculous pleurisy. Gentz reports the case of a man, aged 48, who had had left pleurisy (? tuberculous) in 1904. Two aspirations yielded 1,350 c.cm. of clear fluid. Three years later he began to suffer from dyspnoea and vertigo without objective signs. One week before admission dyspnoea became worse, especially at night, and there was a feeling of epigastric pressure; his general condition was good. The left hemithorax was very retracted, deformed, and almost immobile, with definite thoracic scoliosis. The heart and aorta were dilated and hypertrophied; the blood pressure was 210/150 mm. Skiagrams showed extensive adhesions and left pleuritic calcification. Aspiration in the eighth interspace in the posterior axillary line met with almost bony resistance. About 50 c.cm. of slightly flocculent greenish-yellow sterile fluid containing 2.5 per cent. of albumin was withdrawn. Six days later a second aspiration yielded a similar result, and the subjective symptoms were relieved. In a second case, a man aged 59, and alcoholic, had acute left pleuro-pneumonia in May, 1909. Since then he had had periodic dry cough and effort-dyspnoea. He was admitted in March, 1928, with a diagnosis of chronic gastritis and calculous pleurisy. The left hemithorax was somewhat flattened and smaller than the right, and there was poor air entry. Exploratory puncture in the anterior axillary line was difficult, as the trocar struck a lamella of ivory hardness in the parietal pleura; this was pierced with difficulty. The heart was normal. Skiagrams showed extensive calcification in the left lateral and basal pulmonary regions as high as the fourth rib posteriorly. The patient had evidently had left pleuro-pneumonia nineteen years earlier, leaving adhesions which became calcified or ossified. Skiagrams after supra-laryngeal injection of lipiodol showed that the opacities were extrapulmonary. Gentz adds that these cases prove that a pleuritic exudate may remain *in situ* unabsorbed for many years, and that calcareous deposits may occur in the pleuritic adhesions.

181. Erythema Nodosum and Tuberculosis.

ACCORDING to J. O. SYMES (*Bristol Med.-Chir. Journ.*, Winter, 1928, p. 233) the view that erythema nodosum is allied to tuberculosis is widely held in Europe, and reports, based on clinical findings, have been published by many authors, including Vetlesen, Hambro, and Massini, in support of this contention. Experimental evidence, consisting largely of results of von Pirquet skin tests, is not convincing; examination of the nodes for tubercle bacilli has usually been negative, and animal inoculation has met with scanty success. On the other hand, Wallgren has reported a school epidemic of erythema nodosum which showed an intimate association with tuberculosis. Pollak has stated that this dermatitis is a special form of subcutaneous tuberculide; and Camac Wilkinson asserts that he has never seen erythema nodosum apart from tuberculosis. By those who maintain the existence of this association erythema nodosum has been defined as a tuberculo-bacillaemia, a tuberculo-toxaemia, or an allergic or anaphylactic reaction caused by temporary hypersensitiveness to tuberculosis toxin. Symes has found that in 19 out of 102 cases erythema nodosum was associated with tuberculosis, and is firmly convinced that there is a connexion between the two; he thinks, however, that erythema nodosum is not to be termed a tuberculous disease or the first allergic sign of tuberculosis. He considers that erythema nodosum must always be regarded as a danger signal and timely warning that tuberculosis exists or may develop. Tuberculosis is more likely to follow erythema nodosum in children and young adults, and especially when there is a family or personal history of tuberculosis. The onset of the latter after the development of the nodal fever is the more acute and grave condition. The danger of tuberculous infection is greatest during the first six months following the appearance of the rash, and no patient is safe till three or four years have elapsed, during which period his powers of resistance must be built up.

182. Orchitis as a Cause of Sterility.

F. P. TWINEM (*New England Journ. Med.*, December 20th, 1928, p. 1262) discusses mumps orchitis with special reference to sterility, and reports two cases in which the occurrence of mumps at puberty resulted in sterility on marriage. In all other respects the patients were physically and sexually normal, but spermatozoa were not present in the semen. Examination of the literature shows that in approximately 3 per cent. of all cases of mumps bilateral orchitis develops, with some risk of subsequent sterility. The author considers that sterility due to testicular atrophy following mumps is less rare than is claimed by some observers, and that the condition is often present without any loss of sexual desire or potency and without any abnormality of secondary sex characters. The results of administering diphtheria antitoxin at the onset of mumps to prevent the incidence of orchitis do not appear to be sufficiently appreciable to justify the risk, but the subcutaneous injection of 20 c.cm. of convalescent serum taken from the fifteenth to the twenty-fifth day in uncomplicated cases, and at the time of general recovery in cases of orchitis, seems to be of value in lessening the severity of the attack and in avoiding orchitis. In a severe attack of orchitis with marked swelling incision of the tunica vaginalis with multiple incisions of the tunica albuginea is advocated in order to prevent or lessen testicular atrophy. Further research is needed as to the absence of spermatozoa and the frequency of sterility in cases of bilateral mumps orchitis, and as to the preventive use of convalescent serum in treatment and the value of incisions and diathermy in preventing diminution of testicular function.

183. Narcolepsy.

E. C. THRASH and J. C. MASSEE (*Journ. Amer. Med. Assoc.*, December 8th, 1928, p. 1802) record a case of narcolepsy (one of the few American cases reported), and state that this disease is a clear-cut syndrome characterized by paroxysmal attacks of sleep and usually associated with cataleptic seizures. The attacks of sleep come on frequently during the day; they are irresistible, and may not be relieved by normal sleep at night. The patient may dream during the attacks, may be aroused as from normal sleep, and may feel refreshed on awakening. The cataplectic seizures are characterized by complete loss of voluntary movement and muscle tonus, usually as the result of great emotional stimulus, particularly laughter. Consciousness, however, is not lost in cataplexy. Reference is made to Wilson's paper on narcolepsy (*Brain*, March, 1928) and to the 43 cases reported therein. The present case is considered interesting since there was a definite suggestion of pituitary dystrophy, and the narcoleptic and cataplectic symptoms seemed to have definitely followed injury to the head, points which have been noted in a large percentage of the cases previously reported. The pathology of narcolepsy has not been satisfactorily determined. Some authorities consider that it is due to pituitary disturbance, others have suggested that the malady is caused by disturbances of the structures in the vicinity of the floor of the third ventricle, but the only basis for this opinion is that the subcortical sleep centres lie in this area.

Surgery.

184. Kidney Resection.

A. J. SCHOLL (*Annals of Surgery*, December, 1928, p. 1045) advocates conservative surgical procedures on the kidney. The first reported case of kidney resection was in 1886, but at that time the surgical technique for nephrectomy was more satisfactory, and for many years it was the operation of choice in malignant, tuberculous, and other infectious conditions of the kidney. In recent years, when more satisfactory methods of approach are being employed, and external incisions, such as the postero-lateral, are made that permit visualization of the entire field of the operation, the trend of renal surgery is towards conservation. It is important that, before the vessels of the diseased part are clamped, an adequate blood supply is assured to the sound stump of kidney left behind. After suture the area of resection is covered by a portion of the fatty capsule. Simultaneous resection of both kidneys or simultaneous nephrectomy and resection give a high mortality, but in non-simultaneous operations on both kidneys the results are good. Resection of a kidney should not be performed when the opposite

kidney is doing all the work, since the remaining segment would probably atrophy, having no stimulus to function, and might become a source of infection for the entire urinary tract. In simple infective cases partial nephrectomy should only be employed if the pathological condition is confined to a localized area of the kidney. In cases where a resection is performed to remove an [illegible], even though the incision is made through [illegible] tissue, a local fibrosis is generally present, and haemorrhage is usually slight. An inner suture of continuous catgut will control internal bleeding and a second one approximates the parenchyma and serves as a haemostatic suture. Several interrupted through-and-through catgut sutures are placed through the renal stump, and the incision should then be covered with a flap made from adjacent fatty tissue. The incision should be made so that a wedge of diseased tissue is removed; this permits a more accurate closure of the remaining segment.

185. Congenital Stenosis of the Oesophagus.

C. C. BEATTY (*Brit. Journ. Child. Dis.*, October–December, 1928, p. 237), who has collected fifty cases from the literature up to the end of 1926, in addition to five cases which have come under his own observation, states that congenital narrowing of the oesophagus, apart from complete atresia, is a rare condition. Two distinct types may occur—namely, a membranous type, in which there is partial occlusion of the lumen by a fold of normal mucous membrane, and a non-membranous type, in which there is a localized reduction in the size of the oesophagus. The commonest sites for the stenosis are the upper and lower ends of the tube. In contrast with acquired stenosis, congenital stenosis shows an absence of pathological changes in the walls of the oesophagus, but there may be hypertrophy and dilatation above the obstruction. There are usually no concurrent congenital abnormalities. The onset of symptoms is usually in infancy, especially at the time of weaning, the most characteristic symptom being regurgitation of food a few minutes after deglutition without pain or nausea. Adult patients may be well developed, but some degree of infantilism is not uncommon in children and adolescents. Radiography and oesophagoscopy are invaluable in diagnosis. The prognosis in the membranous type is good, and complete recovery is usually possible. In the non-membranous variety the outlook is not unfavourable as regards life, but severe restrictions in food are generally necessary. The best treatment in the membranous type is gradual dilatation by bougies controlled by oesophagoscopy until the membrane has been destroyed. In the non-membranous type a radical operation may be necessary.

186. Traumatic Cerebro-spinal Meningitis.

A. LODE and F. SCHMUTTERMAYER (*Wien. klin. Woch.*, January 3rd, 1929, p. 5), who record a personal case, illustrate the rarity of traumatic meningococcal meningitis by the fact that Korbsch in 1923 could find only fourteen cases on record, in one of which pneumococcal was associated with the meningococcal infection. The trauma in the various cases consisted of a kick by a horse, a fall in the street, a blow on the forehead and nose, and a nasal operation. In a few cases the meningitis occurred within twenty-four hours of the injury, but usually there was an interval of some days or weeks. In the majority of cases recovery ensued after an illness of one to four weeks. The authors' case was that of an engineer, aged 29, who sustained a fracture of the base of the skull in a motor cycle accident. Six months later he was able to resume his work, but three months afterwards he developed meningitis and died after a week's illness. The necropsy revealed a meningeal exudate containing meningococci at the site of the non-consolidated fracture.

187. Sarcoma in Osteitis Deformans.

G. C. SEGALE (*Arch. Ital. di Chir.*, November, 1928, p. 482) reports two cases of sarcoma developing in patients suffering from osteitis deformans. Since this is a comparatively rare disease and the number of cases developing sarcoma is high, it is tempting to suggest that the peculiar type of inflammation characteristic of osteitis is a predisposing cause. It has been found experimentally that chronic irritation may induce sarcoma, though not so often as carcinoma. The author's first case was a man, aged 66, who had suffered from Paget's disease for five years, and then developed a sarcoma of the right scapula which killed him in six months. The second case was a man, aged 50, with Paget's disease of six years' duration who presented a sarcoma of the humerus, one of the bones affected with osteitis. Spontaneous fracture occurred and the arm was amputated. The local conditions were satisfactory, but six months later the man died from cerebral haemorrhage which was found to be due to a metastatic growth in the brain. In a subsequent note the author refers to a recent paper by Bird, who collected nine cases of osteitis deformans associated with sarcoma.

Therapeutics.

188. The Use of Scarlet Fever Antitoxins.

J. A. TOOMEY and E. G. DOLCH (*Amer. Journ. Dis. Child.*, December, 1928, p. 1173) record a series of 283 patients, moderately or severely ill, treated with scarlet fever antitoxin, and 60 untreated patients of the same type. They used several types of antitoxin, unconcentrated and concentrated. To 54 patients intravenous injections were given, and the remainder were treated intramuscularly. There was no convincing difference between the intramuscularly treated patients and the untreated ones as regards toxicity, duration of rash, or complications. In 14 patients there was pronounced improvement after the intravenous injection of antitoxin, but the remaining 40 did not show any marked betterment as compared with the control cases, and 3 of the 40 died after showing signs of anaphylaxis. The authors found that serum sickness, which occurred in 199 of the treated cases, was usually more severe than the disease itself. They believe that at the present time the evidence in favour of the use of scarlet fever antitoxins is neither clear-cut nor decisive; they have, however, obtained good results with Dick toxin in active immunization. It is suggested that the two organisms of the Dicks may belong to a group the active toxin of any one of which can immunize a person against the other strains in the same group. However, the antitoxin made from these strains might not protect or cure a patient who contracts scarlet fever from another strain of streptococcus.

189. Cardiac Tonic Effect of Embryonic Extract.

N. P. RASOUMOV and A. B. NICOLSKAJA (*Acta Med. Scand.*, December 28th, 1928, p. 436) claim to have had excellent results in the treatment of myocardial weakness by the subcutaneous injection of 0.5 to 1 c.cm. of aqueous extract of the tissues of immature embryo lamb. These results were obtained when camphor, strychnine, digalen, and strophanthus had failed. The authors describe the effects produced by the injections in five young adults—two women and three men. In all these cases the dilated heart became definitely smaller within fifteen minutes after the injection, and the effect persisted for twenty-four hours. Many other patients have received a course of injections without having to discontinue work for more than a few days. After treatment the patients were able to leave the out-patient department within half an hour or an hour. The authors state that it was observed that in several cases, after the failure of ordinary cardiac tonics, the embryonic extract, in addition to its immediate effect on myocardial tone, showed a remarkable secondary action, in that cardiac tonics were effective when administered subsequently although they had failed previously. The authors compared the effects of subcutaneous injections of adrenaline and pituitrin with those of embryonic extract, and report that the action of the former was more transient. It was found that after one to three injections of embryonic extract cardio-tonic and general tonic treatment could be given successfully. No serious complications followed the injections, but occasionally headache, vertigo, and malaise were observed. One patient had a slight rigor after an injection.

190. Vaccine and Bacteriophage Treatment of Typhoid Fever.

R. DORIA (*Il Policlinico*, Sez. Med., December 1st, 1928, p. 653), as the result of his study of 158 typhoid patients, 90 of whom did not undergo any vaccine treatment, came to the following conclusions. (1) In a small percentage of cases vaccine and bacteriophage treatment succeeds in per[illegible] the febrile period at the onset, the height [illegible] the terminal stage of subfebrile tem[illegible] are frequent in inoculated persons, [illegible] and sometimes recurrent; they are not invariably less severe than in the uninoculated. (3) In the majority of the inoculated the duration of stay in bed is about the same as in the non-inoculated, and the incidence of complications and mortality is almost identical. The average temperature, if the pyrexia due to inoculation is included, is not appreciably lowered. (4) Repeated injections of vaccine are not harmless, since they may sometimes give rise to necrosis of the skin, or loss of the intestinal endothelium. This event is dangerous if the patient is in a serious condition and is already suffering from complications. In a certain number of cases collapse may ensue. It does not therefore appear advisable to substitute vaccine therapy for bath treatment in enteric fever, nor to make vaccine therapy part of the routine treatment of the disease. Some advantage, however, may be derived from a prudent use of vaccines in enteric, the indications for their employment being as follows: (1) during the first week in the hope of cutting short the disease,

but without persisting with the treatment if success is not immediately obtained; and (2) in the prolonged subfebrile condition sometimes following typhoid, which is often the expression of a definite localization of *B. typhosus*.

191. Autohaemotherapy in Herpes Zoster.

C. SCUDERO (*Il Policlinico*, Sez. Prat., December 24th, 1928, p. 2556) during the last two years has treated a dozen cases of herpes zoster by injecting the patient's own blood, and reports three examples, in patients aged 22, 24, and 34 respectively. Intragluteal injections of 2 to 15 c.cm. are given every other day. The method is said to be easy to apply and quite harmless. It causes a rapid cessation of the neuralgic pain and disappearance of the vesicles, and prevents the occurrence of neuritis, which may last for months or even years after an attack of herpes zoster.

Ophthalmology.

192. Concomitant Strabismus and Heterophoria.

QUOTING Hartridge's definitions of heterophoria and strabismus, K. R. SMITH (*Brit. Journ. of Ophthalmol.*, November, 1928, p. 581) remarks that, both in squint and heterophoria, monocular instead of binocular vision is the visual defect, and deviation is associated with it. A new definition is needed, therefore, and Smith suggests the following, which covers both conditions: defect of vision in which binocular vision is absent and there is a deviation in the direction of the eyes, so that the visual axes are not directed to the same object. In heterophoria the conditions described are occasional: in squint they are sufficiently constant to be regarded as permanent, and the association of these two abnormalities is too constant to be omitted. By binocular vision is meant central vision with both eyes of the object looked at, straight lines from the object through the nodal points of each eye falling upon the macula of each eye. When there is deviation these lines do not impinge on the macula of each eye. In convergent squint, when the line from the object passes through the nodal point to the macula of one eye, the line from the object through the nodal point of the other eye does not fall on the macula but on the nasal side of it. In divergent squint the cornea is rotated outwards, the macula inwards, the line through the nodal point impinges on the temporal side of the macula in the divergent eye, and the object is displaced to the opposite side. Diplopia is the natural proof that binocular vision does not exist. The nature of the two clinical facts recorded in the definition is made clear as regards convergent squint by one more clinical fact—the period of its appearance, namely, childhood. The arrest of development of binocular vision in hypermetropic children is the cause of convergent concomitant squint. The three factors which concur in producing temporary artificial squint are previous binocular vision, one-eyed sight, and initial movement in the eye which does not see associated with a change of focus (accommodation) in the eye which does. The successful treatment of heterophoria is training the power to retain vision with both eyes at the same time, and the binometer is useful for this purpose. Deviation is the objective sign of absence of binocular vision, and in children is evidence of arrested development of this vision. The power to retain sight in both eyes at the same time can easily be restored and cultivated in children. Smith advocates the systematic use of the binoscope, which induces binocular vision without difficulty and is a successful curative procedure.

193. Tuberculin Therapy in Ocular Tuberculosis.

O. BERGHAUSEN (*Arch. of Ophthalmol.*, November, 1928, p. 583) believes that tuberculous infections of the eye are amenable to tuberculin therapy, and reports seventeen cases, in ten of which both general and ocular improvement quickly followed subcutaneous injections of tuberculin, and the patients were able to resume their occupations. In one case, which showed no improvement, the conclusion was reached that the condition was not tuberculous. In the eye, the lid or the conjunctiva may be the seat of a primary infection from without, though this is very rare. The condition is generally secondary to a focus elsewhere in the body; the infection gains entrance to the eye through the circulation, and is most frequently a metastatic process. Schick recognized three stages in the disease: a primary, in which a small nodule occurs in the iris with a slight area of resorption; a secondary, which shows diffuse iritis and irido-cyclitis with toxic symptoms; and a tertiary, with torpid iritis and later formation of glass-like nodules and precipitates. In ocular tuberculosis there may be found an acute process with hypersensitiveness and a tendency to destruction, or the disease may be of the proliferative type without acute manifestations and with a tendency to connective tissue formation. In the former variety the patients should be treated by rest and general measures without specific medication; in the latter, the patients are frequently benefited by specific treatment. General symptoms are usually not marked in ocular tuberculosis, and since the specific reactions simulate those of syphilis Wassermann tests should always be made. In the present cases tuberculin B.E. and T.R. and the new preparation tebeprotin were used. Berghausen holds that diagnostic tuberculin tests are of value in establishing the proper diagnosis, particularly when accompanied by mild, general, and local reactions. When the condition is associated with symptoms of tuberculosis in other organs, general measures should first be employed; in long-standing or recurring infections of the eye the possibility of an underlying tuberculous infection should be recognized, and general and special examinations be made.

194. Sarcoma of the Iris.

B. CHANCE (*Amer. Journ. of Ophthalmol.*, November, 1928, p. 859) reports a case of sarcoma of the iris which occurred in a man, aged 42. The tumour, a small yellowish-brown mass, was situated at the lower extremity of the meridian, and filled the angle of the chamber. The patient had noticed its presence for at least twenty-seven years, and could assign no cause for it. The eye had never been injured or inflamed, and no ocular pain or temporal or frontal headaches had ever been complained of. As a first step in treatment the mass was excised; four days later an after-cataract was successfully extracted. The tumour proving microscopically to be a mixed-cell sarcoma, the globe was successfully enucleated under local anaesthesia after a further eighteen days. A thorough search of several sections of the excised globe failed to reveal tumour cells in the uvea or nerve. This operation was performed six years ago and the result has been perfectly satisfactory. The orbital tissues are perfectly healthy and the patient maintains good health. C. A. YOUNG (*ibid.*, p. 864) also reports a case of primary melano-sarcoma of the iris. This condition occurs most frequently between the ages of 40 and 60, and is especially characterized by slow growth and the late appearance of inflammatory symptoms. It must be distinguished from syphilis, tuberculosis, granulation tumour surrounding a foreign body, cystic growth of the iris, and melanoma. The patient, aged 30, who was first seen in 1926, gave a history of eye injury nine years previously; two years later he had noticed the small growth in the region of the limbus. The eye was enucleated under ether anaesthesia, with satisfactory results. Up to the time of reporting there have been no signs of recurrence or metastasis. Young states that the presence of a growing tumour in the iris over a period of years does not exclude sarcoma. Enucleation is the safest procedure in iritic sarcoma, and self-cure by the development of phthisis bulbi is not to be expected.

Obstetrics and Gynaecology.

195. Treatment of Utero-vaginal Prolapse.

E. G. ANDERSON (*New Zealand Med. Journ.*, December, 1928, p. 388) believes that the pubo-cervical musculo-fascia, as described by Bonney, constitutes the major vaginal and uterine support; the levatores ani also play their part. He deprecates, therefore, sling operations from above in cases of genital prolapse, and suggests dealing rather with the pelvic floor defect. For prolapse of the first, second, and occasionally of the third degree, Fothergill's operation of anterior colporrhaphy and colpoperineorraphy is the one of choice, but for those cases of the third degree which show vaginal inversion with ulceration of the cervix he combines vaginal hysterectomy with anterior and posterior vaginal repair. Under spinal anaesthesia an area from behind the urethra in front to the posterior fornix behind, and to the sides of the cervix laterally, is mapped out by forceps. This area is denuded and the bladder is dissected from the cervix; the uterus is mobilized by dividing the cervical muscle from the cervico-pelvic ligaments, and an opening is made into the pouch of Douglas and finally into the utero-vesical pouch. The uterus is delivered through the last opening and the tubes, with the round and broad ligaments, are clamped and divided. The ends of these are tied and the ligatures are left long. The peritoneum is then approximated and the tubes, round ligaments, and cervico-pelvic ligaments are tied together below to form a central pivot. To this the vaginal mucous membrane posterior to the cervix is stitched, the opposing vaginal portion of cervico-pubic fascia is approximated to form a support for the bladder, and, lastly, the edges of the vaginal mucosa in front are brought together. When the vagina is inverted following supravaginal hysterectomy the herniated mass is denuded of mucous membrane and the cervix cored out. After fixing a small tube into the

cavity of the cored out cervix the herniated mass is infolded by invaginating sutures. The levatores ani may then be approximated and the vaginal canal obliterated (except for the tube) by bringing together the mucous membrane from behind forwards. The advantages claimed for this method of treatment are (1) a strong and permanent support; (2) absence of shock; and (3) absence of leucorrhœa.

196. Pregnancy and Tumours.

F. C. VAN TONGEREN (*Nederl. Tijdschr. v. Geneesk.*, October 27th, 1928, p. 5308) states that the tumours complicating pregnancy can be classified in three main groups—namely, (1) fibroids, (2) ovarian tumours, and (3) malignant disease of the uterus and surrounding organs. During the period 1915 to 1926 there were 17,439 confinements in the University Women's Clinic at Amsterdam; 32 cases (0.18 per cent.) were complicated by fibroids, 27 (0.15 per cent.) by ovarian tumours, of which one was a fibroma and the rest cysts, and 8 by malignant tumours. The author's treatment of uterine fibroids is much more conservative than it used to be. Whereas formerly it was the practice to remove the myomatous uterus as soon as pregnancy occurred, this operation is now only performed when there is an obstruction to delivery, or when severe abdominal symptoms arise. In the case of ovarian cysts, 13 were removed during pregnancy—7 during the first three months, 5 between the fourth and sixth months, and one in the last three months. The method of treatment of malignant tumours in pregnancy at the Amsterdam Women's Clinic is as follows. In operable cases up to the sixth month of pregnancy inclusive hysterectomy by Wertheim's method is performed, followed by x-ray treatment, and between the eighth and tenth months Cæsarean section, followed by removal of the uterus. In inoperable cases the same treatment is employed, except that supravaginal amputation is substituted for complete hysterectomy, and is followed by x-ray and radium treatment. During delivery rapid Cæsarean section is performed in order to prevent laceration of the carcinomatous tissue, which might give rise to severe haemorrhage and further dissemination of the growth. When delivery has already occurred spontaneously, hysterectomy should be rapidly performed if the carcinoma is still operable.

197. Etiology of Central Rupture of the Perineum.

A. MANDELSTAMM (*Zentralbl. f. Gynäk.*, December 22nd, 1928, p. 3272) remarks that very little is known about the actual cause of central perineal tears; certain conditions of the soft parts or of the pelvis are considered to share the responsibility, but it is regarded as strange that such different occurrences may have the same result. Three cases of central perineal rupture are discussed; all the patients were primiparæ. In one patient labour was protracted with weak pains; in the other two cases the pains were strong. In no instance was the perineum especially high or stiff, but all the patients had flat pelves with narrow inlets, broad outlets, only slight pelvic obliquity, and the vulva placed far forward. The author believes that this type of pelvis accounts for the central rupture. He agrees with Sachs that the head follows every turn of the pelvis. If the vaginal wall projects posteriorly the head is not directed forwards towards the vulva, but, pushing the vaginal wall before it, it presses against the perineum and thus may cause a central tear. Primiparæ, and especially very young women, are particularly liable to this injury, and the author believes that the insufficient tilting of a flat pelvis is an important factor in the causation. This is difficult to estimate, and he has devised an instrument for measuring it.

198. Sulfarsenol in Puerperal Fever.

SINCE January, 1924, M. RIVIÈRE (*Gaz. Hebd. Sci. Méd.*, January 6th, 1929, p. 2) recommends the use of arsenic salts in the treatment of puerperal fever. Encouraged by good results he has, since 1925, aimed at the prevention of puerperal fever by the same means. Arsenic has been given in all cases in which fever might be expected. Rivière's figures for four years are 3,667 accouchements with only three deaths, giving a mortality of 0.08 per cent.; of this number, 169 were definitely septic, though in varying degree. Among them were women who had had multiple interventions before admission to hospital, frequently without aseptic or even antiseptic precautions. The author has now arrived at a systematic method of treatment: at the first rise of temperature of genital origin, without waiting for absolute clinical confirmation, arsenic is administered; subcutaneous injections of sulfarsenol proved most satisfactory. For treatment 0.12 to 0.18 cg. in severe cases was given; this dose was repeated from one to nine times according to the resistance and the gravity of the infection. For prevention 0.06 to 0.12 cg. was found to be adequate. Out of 53 important operations, treated on such preventive lines, in 7 cases there had been infection, and there had been only one death.

Pathology.

199. "Erythroconten" and Pernicious Anaemia.

E. LAUDA and E. FLAUM (*Wien. klin. Woch.*, December 20th, 1928, p. 1737), discuss the red cell inclusions described by Schilling as "erythroconten," and regarded by him as the cause of pernicious anaemia (morbus Biermer). These inclusions are variously shaped rods 2 to 4 μ long, best stained by combined Giemsa and Nile blue sulphate when they appear as pale blue bodies with a tendency to an azure tint. They may occur in small numbers or may be as numerous as plasmodia in a strong malarial infection. The present authors have observed these bodies in great numbers in eight cases, and could not find them in three other cases; they regard them as being quite distinct from any of the accepted forms of blood parasite. Assuming that they might belong to the Bartonella group, the infected blood was inoculated intravenously into splenectomized animals (rats, guinea-pigs, rabbits, a dog, and a macacus), with entirely negative results after six weeks' observation. The fact that Schilling found these bodies in cases of secondary anaemia, lymphatic leukaemia, diabetes, and gastritis indicates that these inclusions are not specific. The authors have also observed them in cases of lead poisoning; they suggest that they are related to the basophil substance of the young erythrocyte, and are disposed to regard them as protoplasmic thickenings resulting from some mechanical influence.

200. Bact. pneumosintes in Influenza.

O. MOLTKE, S. A. LARSEN, and G. KROGH-LUND (*C. R. Soc. de Biologie*, December 7th, 1928, p. 1759), following the technique of Olitsky and Gates, endeavoured to cultivate *Bact. pneumosintes* from twelve cases of influenza in Copenhagen. In the first six cases, besides planting directly on to Smith-Noguchi medium and blood agar and incubating anaerobically, the filtered and unfiltered nasal washings were inoculated into rabbits. In these animals they never detected a rise in temperature, nor a constant mononuclear leucopenia; neither did they succeed in cultivating *Bact. pneumosintes* from the lungs. Although the lungs presented lesions similar to those described by Olitsky and Gates, the same alterations were found in a control rabbit which had been inoculated intratracheally with Ringer's solution. Direct cultivation of the nasal washings after filtration was likewise without result. The authors conclude that this organism cannot be regarded as the specific etiological agent of influenza.

201. Experimental Immunization against Enteric Fever and Dysentery.

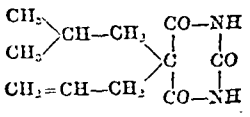
E. FRÄNKEL (*Deut. med. Woch.*, November 9th, 1928, p. 1874) has investigated the possibility of immunizing rabbits which had been rendered typhoid carriers by infection of the gall-bladder; he administered immunoids which contained sodium benzoate and an emulsion of killed typhoid bacilli. It was found that while subcutaneous and peroral administration had no effect, intravenous injection protected five times as many animals from infection as those which had not been so immunized. In subcutaneous infection of a white mouse with *B. paratyphosus* B, the administration of immunoids appeared to cause an increased resistance, and a considerably larger percentage of animals survived than in the case of the controls. Similar results were obtained by infecting the animals with the Breslau variety of paratyphoid bacillus. Administration of immunoids prepared from culture of the Shiga bacillus was followed by a number of animals being protected from subsequent infection, whereas control animals died in two to five days.

202. Relation of Leptospira biflexa to Leptospira icterohaemorrhagiae.

M. SARDJITO and MARGARETE ZUELZER (*Centralbl. f. Bakt.*, January 11th, 1929, p. 180) have investigated the distribution of *Leptospira biflexa* in a number of different water supplies in Sumatra and Java. They find that along the east coast of Sumatra the water is definitely alkaline, and that *L. biflexa* is very abundant. In Java, on the other hand, owing to a different geological conformation, the water is acid and rarely contains this organism. Related to these observations is the fact that cases of Weil's disease are very common in Sumatra, occurring all the year round, whereas in Java they appear comparatively seldom. The authors do not draw any definite conclusions from this relationship, but they emphasize the connexion between the wide distribution of *L. biflexa* in the water supplies of Sumatra and the high incidence of Weil's disease on the one hand, and on the other the practical absence of *L. biflexa* from the water supplies of Java and the correspondingly low incidence of Weil's disease.

SANDOPTAL

A NEW HYPNOTIC



ISOBUTYL-ALLYL-MALONYLUREA

Clinical and laboratory tests have shown that Sandoptal fulfils to a high degree the conditions required in a hypnotic agent.

Sandoptal owes its advantages to a particularly favourable therapeutic index which permits sufficient dosage without harmful after-effects.

Sandoptal is sure and constant in action, and well tolerated by the aged.

It produces tranquil sleep of natural intensity and normal duration, and the awakening is net and accompanied by a feeling of freshness and general well-being.

It has been shown that Sandoptal is rapidly eliminated from the organism and that it does not produce exanthema.

DOSAGE:

Usual dose: 1 tablet, half to one hour before bed-time.

In obstinate cases: 1 to 3 tablets may be given (maximum dose 4 tablets).

TUBES OF 10 AND BOTTLES OF 100 TABLETS.

AGENCY:

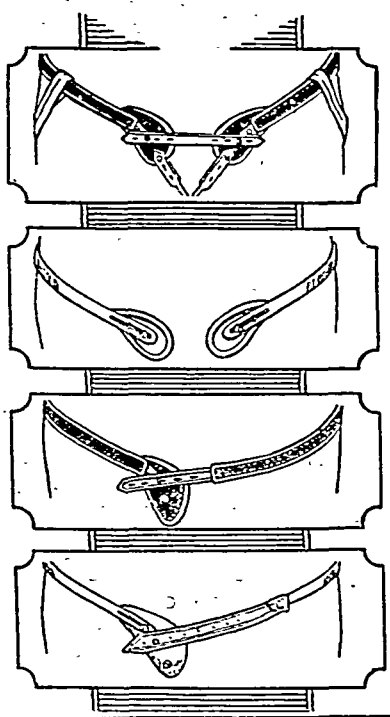
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

The Medical Profession
with the aid of Salt's Surgical Service
CAN
(except in cases of gross carelessness on the Patient's part)
PREVENT
future cases of
SEVERE HERNIA
and greatly alleviate those already existing.



HIGH PRICES NOT ESSENTIAL FOR EFFICIENCY.

An outstanding feature of our Surgical Service is that, taking into consideration price, occupation, and the characteristics of each individual case, we can supply every class of patient with an *Efficient Truss.*

Our Hospital quality truss has the fundamental merits of the more expensive trusses, but is finished with a cheaper covering, etc., which enables us to supply this at a price which is suitable to the poorer class of patients.

Our Ordinary quality truss has a leather lining and covering which proves most durable in cases subjected to hard usage, and has the added advantage of being low in price.

For the patient who is thin, or who requires strong pressure, we supply different types of soft indiarubber pads, while for the man who suffers from excessive perspiration our celluloid truss is especially suitable.

We invite the Medical Profession to compare our prices for special trusses with the high prices charged for so-called "rupture-cure" appliances so extensively advertised to the general public.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT. ESTABLISHED 1793.

COMPLETE STERILIZING OUTFIT

Despatched to Manchuria. Arranged to work by steam or oil.

We are manufacturers of Hospital Theatre equipment, dressings, water, bowl, and instrument sterilizers.

Designs and drawings prepared for any special, novel or experimental apparatus.
